MICROBUNDLES AND SMOOTHING

R. LASHOF and M. ROTHENBERG

(Received 17 February 1964)

INTRODUCTION

In this paper we concern ourselves with the following question. Suppose one has an unbounded combinatorial manifold $K$ contained in an unbounded differentiable manifold $M$. When does there exist a piecewise differentiable isomorphism $h : M \to M$ such that $h(K)$ is a smooth submanifold of $M$. It is clearly necessary that $K$ have a vector bundle neighborhood in $M$. Our main result asserts that if $K$ is the homotopy type of a finite complex the converse is true.

This theorem can be thought of as a refined version of the fundamental theorem of smoothing theory due to Cairns–Hirsch. While the “classical” Cairns–Hirsch theorem is our takeoff point the generalization is not straightforward. Our basic tool is the theory of piecewise linear microbundles due to Milnor [5], and we assume familiarity with these notes. Aside from a strong form of the “classical” Cairns–Hirsch theorem due to Mazur [4] and the notes of Milnor, we utilize techniques and results in differential topology which have already appeared in print.

Chapter I is a bit technical, building up the necessary simplicial machinery. The most important results are in §3, yielding a functorial triangulation in the best possible sense of a vector bundle over a complex. This result appears to have applications beyond the considerations of this paper.

In Part II we apply the machinery of Part I to the problem of smoothing theory. §5 deals with stable tubular neighborhood theorems in the combinatorial category. Here the results are what one would expect and in fact more or less assumed by those working in the field. However, our proof is the first we know of in the general case. It is based on a careful analysis of a proof of Mazur for an important special case. §6 deals with results and application of results concerning the representability of the functor which assigns to each combinatorial manifold its set of smoothings. Here our machinery of Part I pays off in yielding a relatively straightforward and unique proof of a theorem on $\Gamma_n$ due independently to Hirsch and Mazur; along with its generalizations announced by Mazur. Of particular interest may be a proof of a conjecture of Mazur that the set of smoothings of a differentiable manifold form in a natural way an abelian group. In §7 we conclude the paper by proving the theorem promised at the beginning of this introduction.
In a subsequent paper we will apply the machinery developed in this paper to the question of classifying imbeddings of homotopy \(n\)-spheres in \(S^{n+k}\). In particular, we will give there a proof and elaboration of the exact sequences which we announced in Seattle in the Summer 1963.

We might remark that this line of research was inspired by hearing of the result of Hirsch that \(\Gamma_n = \pi_n(PL/O)\) and trying to understand this result. Half-way through our own work we came upon the notes of Mazur [4] which considerably clarified and broadened our outlook as well as supplying some key ideas. We are also indebted to conversations with Hirsch and Mazur at the Seattle conference on Differential Topology.

PART I—SEMI-SIMPLICIAL BUNDLES

51. PIECEWISE DIFFERENTIABLE VECTOR BUNDLES

We begin by constructing a semi-simplicial analogue of the orthogonal group \(O_n\). This will turn out to be more suitable for comparison with Milnor’s semi-simplicial group \(PL_n\) [5], and hence for comparing vector bundles with microbundles.

DEFINITION (1.1). The c.s.s. group \(O_n\).

Let \(\Delta_r\) be the standard \(r\)-simplex, and \(\Delta_r \times \mathbb{R}^n\) the product \(n\)-plane bundle over \(\Delta_r\). An \(r\)-simplex in \(O_n\) is a vector bundle map \(f: \Delta_r \times \mathbb{R}^n \to \Delta_r \times \mathbb{R}^n\) over the identity, which is differentiable over each simplex \(\sigma\) of some rectilinear subdivision of \(\Delta_r\). Composition makes the set \(O_n^{(r)}\) of \(r\)-simplexes into a group. Each monotone simplicial map \(\lambda: \Delta_r \to \Delta_k\) defines a homomorphism \(\lambda^*: O_n^{(k)} \to O_n^{(s)}\) where \(\lambda^* f\) is the vector bundle map over the identity uniquely defined by the condition that

\[
\begin{align*}
\Delta_r \times \mathbb{R}^n &\xrightarrow{\lambda^* f} \Delta_k \times \mathbb{R}^n \\
\Delta_r \times \mathbb{R}^n &\xrightarrow{f} \Delta_r \times \mathbb{R}^n
\end{align*}
\]

commute.

It is easy to check that \(\lambda^* f\) is differentiable over each simplex of a rectilinear subdivision of \(\Delta_r\). Thus \(O_n = \{0_n^{(r)}, \lambda^*\}\) is a c.s.s. group complex.

In the remainder of this section, a complex (unless otherwise specified) will mean a countable, finite dimensional, locally finite, simplicial complex.

DEFINITION (1.2). A piecewise differentiable structure on an \(n\)-plane bundle \(\xi\) over a complex \(K\) is a presentation of the total space \(E(\xi)\) as the union of \(\sigma \times \mathbb{R}^n, \sigma \in K\), with the coordinate transformations from \(\sigma\) to \(\partial_i \sigma\) being in \(O_n^{(r)}\), where \(\dim \sigma = r + 1\).

A vector bundle, together with a piecewise differentiable structure will be called a piecewise differentiable vector bundle (p.d. bundle).

Remark. It follows from the definition, that \(\exists\) a rectilinear subdivision \(K_1\) of \(K\), such
that $\pi^{-1}(\sigma), \sigma \in K_1$, has a well defined differentiable structure, induced from $\tau \times R^n$, where $\tau \in K$ is any simplex containing $\sigma$. We will say that $\xi$ is differentiable over $K_1$.

**Definition (1.3).** Two p.d. bundles $\xi_1$ and $\xi_2$ over $K$ are called equivalent if $\exists$ a map $\varphi : E(\xi_1) \rightarrow E(\xi_2)$ such that $\varphi|_{\pi^{-1}_1(\sigma)} : \pi^{-1}_1(\sigma) \rightarrow \pi^{-1}_2(\sigma)$ is in $O_{\tau}^r$, where $\dim\sigma = r, r \in K$.

**Theorem (1.1).** Two p.d. bundles $\xi_1$ and $\xi_2$ over $K$ are equivalent if and only if they are equivalent as vector bundles.

Before beginning the proof we need the following Lemma which follows immediately from the above remark and Definition (3).

**Lemma.** Two p.d. bundles $\xi_1$ and $\xi_2$ over $K$ are equivalent if and only if $\exists$ a subdivision $K_1$ of $K$ and a map $\varphi : E(\xi_1) \rightarrow E(\xi_2)$ satisfying:

(a) $\xi_1$ and $\xi_2$ are differentiable over $K_1$;

(b) $\varphi|_{\pi^{-1}_1(\sigma)} : \pi^{-1}_1(\sigma) \rightarrow \pi^{-1}_2(\sigma)$ is a differentiable map of differentiable vector bundles, $\sigma \in K_1$.

**Proof of Theorem (1.1).** The "only if" part is obvious. Now assume we have replaced $K$ by a rectilinear subdivision over which $\xi_1$, $\xi_2$ are differentiable. Let $\varphi^0$ be any bundle map of $E(\xi_1) \rightarrow E(\xi_2)$ over the identity. Then $\varphi_0$ is differentiable over the vertices. Now suppose that $\varphi^0$ has been deformed through bundle maps to a bundle map $\varphi^{(r-1)}$ such that $\varphi^{(r-1)}|_{\pi^{-1}_1(\tau)} \rightarrow \pi^{-1}_2(\tau)$ is differentiable, $\tau \in K^{(r-1)}$, $K^{(r-1)}$, the $(r-1)$-skeleton of $K$.

We will show that $\varphi^{(r-1)}$ may be deformed through bundle maps to a bundle map $\varphi^{(r)}$, such that

(a) $\varphi^{(r)}|_{\pi^{-1}_1(K^{(r-1)})} = \varphi^{(r-1)}|_{\pi^{-1}_1(K^{(r-1)})}$

(b) $\varphi^{(r)}$ is differentiable over the $r$-simplicies of $K$. The result will then follow by induction.

Let $\sigma$ be an $r$-simplex. We will consider $\sigma$ to be imbedded in standard fashion in $E'$. Now $\varphi^{(r-1)}$ over $\sigma$ is represented by a continuous map $f : \sigma \rightarrow O(n, R)$, which is differentiable on the boundary $\partial \sigma$ of $\sigma$. It is sufficient to deform $f$ relative to the boundary to a differentiable map. For this will define a deformation of $\varphi^{(r-1)}$ on each $r$-simplex, leaving it fixed over $K^{(r-1)}$, and this deformation may be extended by the homotopy extension principle to a deformation of $\varphi^{(r-1)}$ over $K$ through bundle maps.

Consequently, the theorem will follow if we can prove:

**Lemma.** Let $f : \sigma \rightarrow M$ be a continuous map of an $r$-simplex into a smooth closed manifold $M$, such that $f|_{\partial}$ is smooth, then $f$ may be deformed relative to the boundary to a smooth map.

**Proof.** Let $i : M \rightarrow E^n$ be an imbedding in a sufficiently high dimensional Euclidean space. Let $U$ be a tubular neighborhood of $M$ in $E^n$, and $r : U \rightarrow M$ a smooth retract. It will be sufficient to deform $i : \sigma \rightarrow U \subset E^n$, in $U$, to a smooth map, relative to $\partial$; since the retraction will throw this deformation back into $M$.

By R. Thom, [9], if $\varphi$ may be extended to a smooth map $g$ of some neighborhood of $\varphi$ in $E'$ into $U$, and thus may be extended to a smooth map of $\sigma$ into $U$ (Thom proves a real-valued smooth function on $\varphi$ may be extended to a smooth function on $E'$; the above assertion follows immediately). Since $\varphi$ has a product neighborhood in $\sigma$, it is easy to see
that it may be deformed in $U$ relative to $\sigma$ to a map $\tilde{g}$ which agrees with $g$ on some sufficiently small neighborhood of $\sigma$. But now by the approximation theorem, $\tilde{g}$ is homotopic to a smooth map $h : \sigma \to U$, relative to a closed neighborhood of $\sigma$ in $\sigma$. Thus we get a deformation of it to $h$, relative to $\sigma$; and hence a deformation of $f = rif$ to the smooth map $rh : \sigma \to M$, relative to $\sigma$.

This completes the proof of the Lemma and hence of Theorem (1.1).

**Theorem (1.2).** Every vector bundle over a complex is equivalent to one which admits a p.d. structure.

**Proof of Theorem (1.2).** Imbed $K$ combinatorially in $E^n$, $n$ sufficiently large. Then if $U$ is the interior of the second regular neighborhood of $K$ in $E^n$, $K$ is a deformation retract of $U$; $r : U \to K$ the retraction. Let $n = r^*(\xi)$ then $n|K$ is equivalent as a vector bundle to $\xi$. Since $U$ has a natural differential structure, $E(n)$ can be given the structure of a differentiable vector bundle. Let $K_i$ be a sufficiently fine rectilinear subdivision of $K$, such that each simplex $\sigma \in K_i$ is contained in a coord. neigh. $V_{\sigma}$ of $n$. Then the diff. coord. transformation from $V_{\Delta_i}$ to $V_{\sigma}$ restricts to a diff. coord. transformation from $\partial \sigma$ to $\sigma$, and makes $n|K$ a p.d. vector bundle, equivalent to $\xi$ as a vector bundle.

This completes the proof of Theorem (1.2).

Theorem (1.1) and Theorem (1.2) give

**Theorem (1.3).** An equivalence class of vector bundles over a complex $K$ determines a unique equivalence class of piecewise differentiable vector bundles over $K$, and conversely.

Theorem (3) enables us to treat vector bundles semi-simplicially, the same way Milnor [5] treats p.l. micro-bundles.

**Definition (1.4).** Let $\xi$ be a p.d. vector bundle over a finite complex $K$. We define the associated principal (s.s.) bundle $\vec{\xi}$ as follows; The base space $\vec{\xi}$ is the c.s.s. complex consisting of monotone simplicial maps $f : \Delta_k \to K$; with $\lambda^* : \vec{\xi}^{(k)} \to \vec{\xi}^{(e)}$ defined by $\lambda^* f = f \circ \lambda$.

A $k$-simplex of the total space $\vec{\xi}$ consists of

1. a $k$-simplex $\sigma \in \Delta_k^{(k)}$
2. a p.d. bundle equiv. $F : \Delta_k \times \mathbb{R}^n \to f^*\xi$.

The functions $\lambda^* : \vec{P}^{(k)} \to \vec{P}^{(l)}$ are defined by the formula $\lambda^*(f, F) = (f \circ \lambda, \lambda^* F)$. The right translation function $\vec{P} \times O_n \to \vec{P}$ is just the operation of composing p.d. bundle equivalences. Since $O_n^{(k)}$ operates freely in $\vec{P}^{(k)}$, with orbit set $\vec{R}^{(k)}$; it follows that $\vec{\xi}$ is a principal s.s. $O_n$-bundle.

**Lemma.** Two p.d. vector bundles $\xi, \eta$ over a complex $K$ are equivalent if and only if the associated c.s.s. principal bundles $\vec{\xi}, \vec{\eta}$ are equivalent.

(Proof as in Milnor [5], p. 25)

**Lemma.** Let $K$ be a complex. Any principal $O_n$-bundle $\pi$ over $\vec{K}$ is isomorphic to $\xi$ for some p.d. vector bundle $\xi$ over $K$.

**Proof.** (As in Milnor, [5], p. 26).

By Heller's classification theorem [1], we have
The equivalence classes of n-dimensional p.d. vector bundles and hence (Theorem (1.3)) the equivalence classes of n-dimensional vector bundles over a complex K are in 1-1 correspondence with the homotopy classes of (s.s.) maps of $K$ into the base space of any universal (s.s.) bundle for $O_n$.

In the remainder of this paper we assume familiarity with elementary piecewise linear micro-bundle theory, as contained in Milnor [5]. In particular, the definition and properties of the piecewise linear complex of $n$ germs, $PL_n$, is assumed.

2. THE C.S.S. COMPLEX $PD_n$

Definition (2.1). A map $f : K \to M$ of a simplicial complex $K$ into a smooth manifold $M$ is called piecewise differentiable (p.d.), if $f$ is differentiable on each simplex of a rectilinear subdivision of $K$.

Definition (2.2) $PD_n$. A $k$-simplex in $PD_n$ is a germ of a topological microbundle equivalence $f : \Delta_k \times R^n \to \Delta_k \times R^n$ (i.e. $f$ is fibrewise and preserves zero section), such that $f : \Delta_k \times R^n \to \Delta_k \times R^n \subset R^k \times R^n$ is a p.d. imbedding w.r.t. the product triangulation of $\Delta_k \times R^n$. The set of $k$-simplicies is denoted $PD_n^{(k)}$. For each monotone simplicial map $\lambda : \Delta_l \to \Delta_k$ define a function $\lambda^* : PD_n^{(k)} \to PD_n^{(l)}$ by $\lambda^*(f)$ is the germ of the topological microbundle equivalence $\lambda f$ uniquely defined by the condition that

$$
\begin{align*}
\Lambda_l \times R^n & \xrightarrow{\lambda \times I} \Lambda_l \times R^n \\
\Delta_k \times R^n & \xrightarrow{\lambda \times I} \Delta_k \times R^n
\end{align*}
$$

commutes.

It is easy to check that $\lambda f$ is a p.d. imbedding. Thus $PD_n = \{PD_n^{(k)}, \lambda^*\}$ is a c.s.s. complex. It is also easy to check that it satisfies the Kan condition [7].

Although $PD_n$ is not a group complex, it contains $PL_n$ and we will see that the inclusion is a homotopy equivalence. $PD_n$ has the advantage over $PL_n$ that $O_n$ acts freely on it.

Definition (2.3). Consider $K$ to be a rectilinear simplicial complex in some $R^n$, and let $f : K \to M$ be a p.d. map into a smooth manifold, i.e. $f$ is differentiable on each simplex of a subdivision $K_1$ of $K$. Then a p.d. map

$$f_x : St(x, K_1) \longrightarrow \tau(f_x)$$

(the tangent space to $M$ at $f x$)

is defined by $f_x(y) = (f|\sigma)_x(y), x \in \sigma \in K_1^k, y \in \sigma \subset St(x, K_1)$, where $(f|\sigma)_x$ is the induced map on tangent spaces (and we identify the tangent space to $\sigma$ at $x$ with $\sigma$).

The map $f$ is called regular if $f_x$ is 1-1 (into) for every $x \in K$. It is called non-singular if it is a regular p.d. imbedding. A non-singular p.d. homeomorphism of $K$ onto $M$ is called a smooth triangulation.

Lemma (Milnor [6]). A p.d. imbedding $f : K \to M$ which is a homeomorphism onto, is non-singular (and hence a smooth triangulation).

Remark. A map $f : \Delta_k \times R^n \to \Delta_k \times R^n$ representing an element of $PD_n^{(k)}$ is nonsingular.
In fact, since \( \partial \Delta_k \) has a product neighborhood in \( R^k \), \( f \) may be extended to a p.d. imbedding of \( N \times R^s \) onto an open set in \( N \times R^n \), where \( N \) is an open neighborhood of \( \Delta_k \) in \( R^k \). By the lemma, the extension of \( f \), and hence \( f \) itself, is non-singular.

**Definition (2.4).** A piecewise differentiable isotopy between two p.d. imbeddings \( f_0, f_1 : K \rightarrow M \) is a p.d. imbedding \( F : K \times I \rightarrow M \times I \), such that \( F_t : K \times t \rightarrow M \times t \) and \( F[K \times 0] = f_0, F[K \times 1] = f_1 \).

**Remark.** If \( F \) is non-singular, \( F_t \) is non-singular.

**Lemma.** Let \( F \) be a p.d. isotopy between \( f_0, f_1 : K \rightarrow M \), and \( G \) a p.d. isotopy between \( f_1, f_2 : K \rightarrow M \), then \( H : K \times I \rightarrow M \times I \), \( H_t = F_{2t}, 0 \leq t \leq 1/2, H_t = G_{2t-1}, 1/2 \leq t \leq 1 \), is a p.d. isotopy between \( f_0 \) and \( f_2 \).

We need two theorems of Whitehead [11].

**Theorem (A).** Let \( f : K \rightarrow R^q \) be a non-singular p.d. imbedding. Then there are maps \( \xi, \eta : K \rightarrow R_+ \) such that every \((\xi, \eta)\)-approximation to \( f \) is non-singular.

An \((\xi, \eta)\)-approximation to \( f \) is a p.d. map \( g : K \rightarrow R^q \), such that \( |g(x) - f(x)| < \xi(x), |g(x) - f(x)| \leq \eta(x) |f(x)| \) \( x \in K, x + y \in St(x, K_1) \), where \( K_1 \) is a rectilinear subdivision of \( K \) on the simplices of which both \( f, g \) are differentiable.

**Theorem (B).** Let \( f : K \rightarrow R^q \) be a non-singular p.d. imbedding, then for any \( \xi, \eta : K \rightarrow R_+ \), there exists a subdivision of \( K \), such that the linear approximation to \( f \) is an \((\xi, \eta)\)-approximation.

The linear approximation of \( f \) w.r.t. the subdivision \( K_1 \) of \( K \), is the p.l. map \( g \) defined by \( g(\Sigma s_i a_j) = \Sigma s_j f(a_j) \), where \( (a_0, ..., a_1) \) is an \( r \)-simplex in \( K_1 \), and \( s_j \) are the barycentric coordinates of a point in the \( r \)-simplex.

From Theorems (A) and (B) we have:

**Theorem (C).** Let \( f : K \rightarrow R^q \) be a non-singular p.d. imbedding, let \((\xi, \eta)\) be given, then there exists a rectilinear subdivision \( K_1 \) of \( K \), such that the \( K_1 \) linear approximation \( g \) to \( f \) satisfies

(a) \( g \) is a non-singular imbedding.
(b) \( g \) is an \((\xi, \eta)\)-approximation to \( f \).
(c) \( F : K \times I \rightarrow R^q \times I \) given by \( F(x, t) = (1 - t)f(x) + tg(x) \) is a p.d. isotopy.
(d) \( F \) is a non-singular imbedding (in \( R^q \times R^1 \)).
(e) If \( f \) is p.l. on some subcomplex \( L \) of \( K \), \( F_L|_L = f \).

**Proof.** (a), (b), (c), (e) are immediate from Theorem (A) and (B). To see (d), note that \( F \) will be an \((\xi', \eta')\)-approximation to \( f \times 1 \), if \( g \) is an \((\xi, \eta)\)-approximation to \( f \) for sufficiently small \((\xi, \eta)\). But \( f \times 1 \) is clearly non-singular.

**Theorem (2.1).** Let \( f : \Delta_k \times R^q \rightarrow \Delta_k \times R^q \) be a topological micro-bundle equivalence, and a p.d. imbedding with respect to the product triangulation of \( \Delta_k \times R^q \) (as a map into \( R^q \times R^q \)). Then there exists a non-singular p.d. isotopy

\[
F : I \times \Delta_k \times R^q \rightarrow I \times \Delta_k \times R^q
\]

† See proof of Theorem (9) of [11].
such that

(a) $F$ is a topological microbundle equivalence (over $I \times \Delta$).
(b) If $f$ is p.l. in some subcomplex $K$ of a rectilinear subdivision of $\Delta_k \times R^n$, then $F_1|_K = f$.
(c) $g = F_1$ is a p.l. microbundle equivalence (over $\Delta$)

$$g : \Delta_k \times R^n \longrightarrow \Delta_k \times R^n.$$  

Proof. Since $f$ is p.l. on $\Delta_k \times 0$ and $K$, it is enough to apply Theorem (C) and show that $\pi F_i = F_i \pi$, $\pi : \Delta_k \times R^n \rightarrow \Delta_k$ the projection. Let $L$ be the rectilinear subdivision of the product triangulation of $\Delta_k \times R^n$ given by Theorem (C). Let $(a_0, \ldots, a_r)$ be an $r$-simplex in $L$. Then by assumption $\pi f(a_j) = f a_j = \pi a_j$ Now let $(\sum_s a_j), \sum_s j = 1$, be an arbitrary point in the $r$-simplex. Then

$$F_1(\sum_s a_j) = (1 - t) f(\sum_s a_j) + t \sum_s f(a_j)$$

$$\pi F_1(\sum_s a_j) = (1 - t) f(\sum_s a_j) + t \sum_s \pi a_j.$$  

But since we have a rectilinear subdivision of the product triangulation of $\Delta_k \times R^n, \pi \sum_s a_j - \sum_s \pi a_j$, and $\pi F_1(\sum_s a_j) = \pi(\sum_s a_j) = F_1(\sum_s a_j).$

Theorem (2.2). $PL_n$ is a deformation retract of $PD_n$.

Proof. We rely on Proposition (1) of Appendix A to Chapter I in [7].

Proposition (Moore [7]). If $X$ and $Y$ are s.s. complexes, then $f_0, f_1 : X \rightarrow Y$ are homotopic if and only if there exists functions $K_i : X^{(q)} \rightarrow Y^{(q+1)}$ defined for $i = 0, \ldots, q$, and all $q$ such that

1. $\partial_0 k_0 = f_1$
2. $\partial_{q+1} k_q = f_0$
3. $\partial_+ k_j = k_{j-1} \partial_i$, $i < j$
4. $\partial_{q+1} k_{q+1} = \partial_{j+1} k_j$
5. $\partial_+ k_j = k_{j+1} \partial_i$, $i > j$
6. $\partial_k k_j = \partial_{k+1} k_{j-1}$
7. $\partial_+ k_j = k_{j+1} \partial_i$

If $A$ is a subcomplex of $X$, and $f_0|A = f_1|A$, then $f_0$ is homotopic to $f_1$ relative to $A$ if and only if

$k_i(\sigma) = f_0(s_i(\sigma)), \quad \sigma \in A.$

We apply this to our problem in taking $f_0 = \text{identity on } PD_n$, $f_1 = \text{retraction of } PD_n$ into $PL_n \subset PD_n$. We use the following:

Lemma. Let $\tau \in PD_n^{(q)}$, and $g_0 : \Delta_q \times R^n \rightarrow \Delta_q \times R^n$ be a p.d. imbedding representing $\tau$. Then if $g : I \times \Delta_q \times R^n \rightarrow I \times \Delta_q \times R^n$ is a p.d. isotopy and a topological microbundle equivalence, such that $g|0 \times \Delta_q \times R^n = g_0$, there exist functions $k_i : L(\tau^{(q)}) \rightarrow PD_n^{(q+1)}$, satisfying (1)-(7) above, where $L(\tau)$ is the subcomplex of $PD_n$ generated by $\sigma, f_0 = \text{identity,}$

$$f_1(\lambda^* \sigma) = \lambda^* (g_1), \lambda \text{ any monotone simplicial map of } \Delta_q \rightarrow \Delta_q.$$

Proof. Subdivide $I \times \Delta_q$ into the $q + 1$ simplicies $(a_0, \ldots, a_{q-1}a_q \ldots a_p)$. Define $k_0(\lambda^*(i)) = (\lambda^* \times I \sigma|\pi^{-1}(a_0, \ldots, a_{q-1}a_q, \ldots, a_p)$. We leave it to the reader to check properties (1)-(7).

In order to prove the theorem, we need to pick representatives $g$ for each non-degenerate simplex $\tau$. Then by Theorem (1), there exists a p.d. isotopy $g$ from $g_0$ to a p.l. homeomorphism $\varphi_1$, relative to any sub-complex on which $g_0$ is a p.l. homeomorphism. We must
show that the isotopy given for the representative of $\tau$ and the representative of $\partial_1 \tau$ agree in some neighborhood of the zero-section over $\partial_1 \Delta_p$. To do this, we proceed by induction. We assume the isotopies have been defined for representatives of all $p - 1$ simplexes to satisfy the above condition. This means that we have a well defined isotopy of $g_0$ on some neighborhood of the zero section above the complete boundary of $\Delta_p$. Now there is a $p.l.$ isotopy of $\Delta_p \times \mathbb{R}^n$ into itself which is a deformation of the identity to a map into any prescribed neighborhood of the zero section, relative to any smaller neighborhood of the zero section. Assuming inductively that our isotopies are always constant for some initial and final interval in some neighborhood of the zero section; Theorem (1) and the above deformation, show that it agrees in some neighborhood of the zero section with the isotopies defined over the boundary, and satisfies the stationary condition on (possibly smaller) initial and final intervals. (Note that any $p.d.$ isotopy above the boundary of $\Delta_p$ may be extended to a $p.l.$ isotopy over $\Delta_p$, since the boundary has a product neighborhood in $\Delta_p$. Also once $g_0$ over the boundary of $\Delta_p$ has been deformed to a $p.l.$ map, application of Theorem (1) leaves this part of the map unchanged.)

§3. ON TRIANGULATING VECTOR BUNDLES—EXISTENCE AND UNIQUENESS

Proposition (3.1). Let $\xi_1$, $\xi_2$ be differentiable vector bundles over a smooth manifold $M$. Let $f : K \to M$ be a smooth triangulation. Then if $\phi : E(\xi_1) \to E(\xi_2)$ is a $p.d.$ vector bundle map over the identity (i.e. $\phi$ is differentiable over each simplex of some rectilinear subdivision $K_1$ of $K$), $\phi$ is isotopic through $p.d.$ bundle maps to a differentiable bundle map.

Proof. Let $P_1$, $P_2$ be the total space of the associ. prin. diff. bundle. Then $\phi$ induces $\Phi : P_1 \to P_2$, a bundle map diff. over each simplex of $K_1$. Now $\Phi$ is defined by a cross-section of the following bundle ($G = \text{group of orthogonal transformations of } \mathbb{R}^n$):

$$
\begin{array}{ccc}
\text{d}^*(P_1 \times_g P_2) & \longrightarrow & P_1 \times_g P_2 \\
\downarrow & & \downarrow \\
M & \longrightarrow & M \times M.
\end{array}
$$

This is a diff. bundle with fibre $G$ and group $G \times G$. Consequently, it may be approx. by a diff. cross-section $\Psi$. Now put a Riemannian metric on $G$, invariant under the action of $G \times G$. Then if $\Psi$ is sufficiently close to $\Phi$, $\Psi(x) = \Phi(\xi)$ may be joined to $\Phi(\xi)$, $\forall \xi \in M$, by a unique shortest geodesic, in the fibre over $\xi$. Deforming $\Phi$ to $\Psi$ along the geodesics preserves differentiability, whenever $\Phi$ and $\Psi$ are both diff; i.e. over each simplex of $K_1$. This defines a $p.d.$ bundle deformation of $\phi$ to a diff. bundle map $\Psi$.

Definition (3.1). Triangulation of $p.d.$ vector bundles. A triangulation of a $p.d.$ vector bundle $\xi$ over a complex $K$, is a $p.l.$ microbundle $\mu$ over $K$ and a fibrewise map $\phi : E(\mu) \to E(\xi)$, preserving the zero cross-section, and such that $\phi$ is a $p.d.$ homeomorphism over each simplex $\sigma \in K$. We denote such a triangulation by the pair $(\mu, \phi)$.

Theorem (3.1). Let $\xi$ be a $p.d.$ vector bundle over $K$, and $(\mu_i, \phi_i)$, $i = 1, 2$ be triangulations
of \( \xi \). Then there exists a map of p.l. microbundles \( \psi : E(\mu_1) \to E(\mu_2) \) such that

\[
\begin{array}{ccc}
E(\mu_1) & \xrightarrow{\psi} & E(\xi) \\
\downarrow \ & & \downarrow \\
E(\mu_2) & \xrightarrow{\varphi_2} & E(\xi_2)
\end{array}
\]

commutes up to homotopy. (Note that \((\mu_1, \varphi_2)\) is a triangulation of \( \xi \), and the homotopy between \( \varphi_2 \psi \) and \( \varphi_1 \) is to be a triangulation at each stage.)

**Corollary.** Let \((\mu_i, \varphi_i)\) be triangulations of p.d. vector bundles \( \xi_i, i = 1, 2 \) over rectilinear subdivisions of \( K \). If \( \lambda : E(\xi_1) \to E(\xi_2) \) is a p.d. bundle equivalence, there exists a microbundle equivalence \( \psi : E(\mu_1) \to E(\mu_2) \) such that

\[
\begin{array}{ccc}
E(\mu_1) & \xrightarrow{\psi} & E(\xi_1) \\
\downarrow \ & & \downarrow \lambda \\
E(\mu_2) & \xrightarrow{\varphi_2} & E(\xi_2)
\end{array}
\]

commutes up to homotopy.

(Note that \((\mu_1, \lambda \varphi_1)\) and \((\mu_2, \varphi_2 \psi)\) are triangulations of \( \xi_2 \), and the homotopy is to be a triangulation at each stage.)

**Proof of Theorem (3.1).** The idea of the proof is to deform \( \varphi_1 \) fibrewise and relative to the zero section to a p.l. homeomorphism \( \psi \) with respect to the triangulation \((\mu_2, \varphi_2)\) of \( E(\xi) \). We do this by induction over the skeletons of \( K \).

But first we may change \( E(\mu_i), i = 1, 2 \) to equivalent microbundles, so that \( E(\mu_i) = \cup \sigma \times R^n, \sigma \in K; (\sigma \times R^n) \) attached to \( \partial \sigma \times R^n \) by a p.l.h. of \( \sigma \times R^n \) over \( \partial \sigma \) into \( \partial \sigma \times R^n \).

Over each vertex \( v \in K^{(0)} \), \( \varphi_1 \) is a p.d.h. of \( (R^n, 0) \) into \( (R^n, 0) \), and is isotopic through p.d. homeomorphisms relative to \( 0 \in R^n \), to a p.l. homeomorphism (see Theorem (2.1)) w.r.t. the triangulation induced by \((\mu_2, \varphi_2)\). This isotopy of \( \varphi_1 |_{\pi_1^{-1}(K^0)} \) may be extended to a fibrewise isotopy of \( \varphi_1 \) on \( E(\mu_1) \) relative to the zero section, p.d. over each simplex; by induction over the skeletons, using the fact that the boundary of each simplex has a product neighborhood in the simplex.

Now assume that \( \varphi_1 \) is a p.l. homeomorphism over the \((r - 1)\)-skeleton of \( K \), and preserves the zero section; and let \( \sigma \) be an \( r \)-simplex of \( K \). \( \varphi_1 |_{\pi_1^{-1}(\sigma)} \) is a p.d.h., which is p.l. over \( \delta \) and p.l. on the zero section. By Theorem (2.1) we can deform \( \varphi_1 |_{\pi_1^{-1}(\sigma)} \) fibrewise, through p.d. homeomorphisms, and relative to \( \varphi_1 |_{\pi_1^{-1}(\sigma)} \) (and the zero section), to a p.l.h w.r.t. \((\mu_2, \varphi_2)\). This, having been done for each \( r \)-simplex, gives a p.d. isotopy of \( \varphi_1 \) over \( K^{(r)} \) relative to \( K^{(r-1)} \) and the zero section. This isotopy may now be extended to a p.d. isotopy of \( \varphi_1 \) relative to \( \pi_1^{-1}(K^{(r-1)}) \) and the zero section.

This completes the induction step and the proof of Theorem (3.1).
THEOREM (3.2). There exists a unique function $T$, functorial in the base space, from equivalence classes of $n$-dimensional p.d. vector bundles (and hence ordinary vector bundles) to equivalence classes of $n$-dimensional p.l. microbundles, satisfying

(a) Given a p.d. vector bundle $\xi$, if $\mu \in T[\xi]$, there exists a map $\varphi : E(\mu) \to E(\xi)$, such that $(\mu, \varphi)$ is a triangulation of $\xi$.

Proof. The uniqueness follows from Theorem (3.1). To show existence, we first define a map of $B_0$ into $B_{PL}$. Let $PD_n$ be the c.s.s. complex defined previously; i.e. a $k$-simplex of $PD_n$ is a fibre preserving p.d. homeomorphism

$$f : \Delta_k \times R^n \to \Delta_k \times R^n, f|_{\Delta_k \times 0} = \text{identity.}$$

$PD_n = \{PD^{(k)}_n, \lambda^n\}$. We recall that $PD_n$ is not a group complex, but has the following properties:

(a) $O_n, PL_n \subset PD_n$

(b) $\pi_i(PL_n) \to \pi_i(PD_n)$ is an isomorphism, all $i$

(c) $PL_n$ acts freely on the right of $PD_n$, $O_n$ acts freely on the left of $PD_n$.

Let $U_n$ be the total space of a universal s.s. bundle for $PL_n$. Then $\pi_1(U_n) = 0$, all $i$. Let $PL_n$ act on both factors of $PD_n \times U_n$. Then $\pi_i((PD_n \times U_n)/PL_n) = 0$, all $i$; since $(PD_n \times U_n, PL_n, (PD_n \times U_n)/PL_n)$ is a principal s.s. bundle (and hence has an exact homotopy sequence), and $\pi_i(PL_n) \to \pi_i((PD_n \times U_n)/PL_n)$ is an isomorphism, all $i$.

Let $O_n$ act on $PD_n \times U_n$ by acting on $PD_n$ only. Then the action of $O_n$ commutes with the action of $PL_n$, and $O_n$ acts freely on $(PD_n \times U_n)/PL_n$. Hence $(PD_n \times U_n)/PL_n, O_n, O_n\backslash PD_n \times U_n/PL_n$ is a universal s.s. bundle for $O_n$. Write $BO_n = O_n\backslash PD_n \times U_n/PL_n$, and $BPL_n = U_n/PL_n$. Then the projection $p_2 : PD_n \times U_n \to U_n$ induces a s.s. map $p : BO_n \to BPL_n$ by passage to the quotients. We note for future use

LEMMA (3.3). $(BO_n, PD_n/O_n, BPL_n)$ is a s.s. fibre space.

Now let $\xi$ be a p.d. vector bundle over some rectilinear subdivision of $K$, and $\xi$ the associated principal s.s. bundle. Then $\xi$ is equivalent to a bundle induced by a s.s. map $f : K \to BO_n$. But $pf : K \to BPL_n$ induces a principal s.s. bundle over $K$ with group $PL_n$. Let $\mu$ be the associated microbundle. We set $T[\xi] = [\mu]$. Since any two classifying maps are homotopic, $T$ is well-defined.

We wish to define a map $\varphi : E(\mu) \to E(\xi)$ such that $(\mu, \varphi)$ is a triangulation of $\xi$. This is done as follows:

If $\sigma \in \bar{K}(\sigma)$, choose $y_\sigma \in U^{(\sigma)}_\mu$ which lies over $p_f(\sigma)$. Further choose $x_\sigma \in PD^{(\sigma)}_n$ so that $(x_\sigma, y_\sigma) \in PD_n \times U_n$ lies over $f(\sigma)$; and denote the class of $(x_\sigma, y_\sigma)$ in $(PD_n \times U_n)/PL_n$ by $[x_\sigma, y_\sigma]$. Then

$$\partial_i y_\sigma = y_{\partial_i\sigma} \cdot F, \quad F \in PL_n^{(q-1)},$$

and

$$\partial_0 [x_\sigma, y_\sigma] = [\partial_0 x_\sigma, \partial_0 y_\sigma] = [x_{\partial_0\sigma}, y_{\partial_0\sigma}]G, \quad G \in O_n^{(q-1)},$$
where we define right action of $G$ by

$$[\partial(x_{\partial}, y_{\partial})] = [G^{-1}x_{\partial}, y_{\partial}]$$

By definition $E(\mu) = \bigcup_{\sigma \in K} \sigma \times R^n$, with $\sigma \times R^n$ identified with $\partial_0 \sigma \times R^n$ by $F, E(\xi) = \bigcup_{\sigma \in K} \sigma \times R^n$, with $\sigma \times R^n$ identified to $\partial_0 \sigma \times R^n$ by $G$. (Here $\sigma \in K$ is considered as the simplex in $R(\sigma)$ representing it.) To define $\varphi$, it is sufficient, in view of Theorem (1), to consider $E(\xi)$ to be the equivalent bundle above. Define $\varphi$ by

$$\varphi|\sigma \times R^n = x_{\sigma}, \quad \sigma \in K.$$ We claim this is well-defined; in fact

$$G^{-1}x_{\partial} = \partial x_{\partial} \cdot F^{-1},$$

since $[\partial x_{\partial}, y_{\partial}] = [\partial x_{\partial}, y_{\partial}] = [\partial x_{\partial} F^{-1}, y_{\partial}] = [G^{-1}x_{\partial}, y_{\partial}]$.

It follows that $\varphi$ is well-defined, and $(\mu, \varphi)$ is a triangulation of $\xi$.

This completes the proof of Theorem (3.2).

§4. ON WHITNEY SUMS

Let $\alpha \in PD_k, \alpha: \Delta_0 \times R^k \to \Delta_0 \times R^k$ and $\gamma \in PD_n, \gamma: \Delta_0 \times R^n \to \Delta_0 \times R^n$ define the Whitney sum $\alpha \oplus \gamma \in PD_{k+n}, \alpha \oplus \gamma: \Delta_0 \times R^k \times R^n \to \Delta_0 \times R^k \times R^n$ by $\alpha \oplus \gamma(x, u, v) = (x, \alpha(x, u), \gamma(x, v))$ where $\alpha(x, u) = (x, \alpha_1(x, u), \gamma_1(x, v))$ then $\oplus$ is a semi simplicial map

$$\oplus: PD_k \times PD_n \to PD_{k+n}. \quad \text{By restriction, we get}$$

$$\oplus: PL_k \times PL_n \to PL_{k+n}$$

$$\oplus: O_k \times O_n \to O_{k+n}.$$ By product action $O_k \times O_n$ acts on $PD_k \times PD_n$ and we have a commutative diagram

$$\begin{array}{c}
(O_k \times O_n) \times (PD_k \times PD_n) \longrightarrow PD_k \times PD_n \\
\oplus \times \oplus \downarrow \downarrow \oplus \\
O_{k+n} \times PD_{k+n} \longrightarrow PD_{k+n}. \\
\end{array}$$

Thus the above map passes to quotients

$$\oplus: PD_k/O_k \times PD_n/O_n \longrightarrow PD_{k+n}/O_{k+n}.$$ We use $[\quad]$ to denote semi simplicial homotopy classes of maps.

Let $K$ be a complex $\alpha_k: K \to PD_k, \alpha_n: K \to PD_n$ then the above operation induces a map $\alpha_k \oplus \alpha_n: K \to PD_{k+n}$. Notice $(\alpha_k \oplus \alpha_n) \oplus \alpha_c = \alpha_k \oplus (\alpha_n \oplus \alpha_c)$.

**Homotopy commutativity of Whitney sums**

(We use $\sim$ for homotopy equivalence of maps)

The vertices of $O_n$ are just the general linear group $GL_n$. Let $w \in GL_n$ and $W$ the smallest
subcomplex of $O_n$ containing $w$. For any complex there is a unique map $w^K : K \to W$. Since $\pi_0(O_n) = \mathbb{Z}_2$, $w_1^K \sim w_2^K$ in $O_n$ iff $\det w_1 \cdot \det w_2 > 0$. Since each $W \subseteq PL_n$ we have a commutative diagram

$$
\begin{array}{c}
K \xrightarrow{w^K} W \\
\downarrow \quad \downarrow \quad \downarrow \\
PD_n \xrightarrow{w,K} PD_n/O_n
\end{array}
$$

Now assume $\det w_1 \cdot \det w_2 > 0$. Since $w_1^K \sim w_2^K$ in $O_n$, $w_1^K \sim w_2^K$ in $PD_n$. Since $i : PL_n \to PD_n$ is a homotopy equivalence $w_1^K \sim w_2^K$ in $PL_n$. Let $A_n$ be one of the complexes $O_n, PL_n, PD_n, PD_n/O_n$. Then using the group structure in $PL_n, O_n$ and their actions on $PD_n$ we have maps

$$
\begin{array}{c}
W \times A_n \longrightarrow A_n \\
A_n \times W \longrightarrow A_n
\end{array}
$$

Thus given a map $\alpha : K \to A_n$ we have products $w^K \cdot \alpha : K \to A_n$ and $\alpha \cdot w^K : K \to A_n$. Using the homotopy equivalence between $w_1^K$ and $w_2^K$ for $w_1, w_2 \in GL_n$ one has $w_1^K \cdot \alpha \sim w_2^K \cdot \alpha$ and $\alpha \cdot w_1^K \sim \alpha \cdot w_2^K$.

Consider $e_n \in GL_n$, the identity matrix, then $e_n^K \cdot \alpha = \alpha = \alpha \cdot e_n^K$. Thus for any $w \in GL_n$, $\det w > 0$, $w^K \cdot \alpha \sim \alpha \sim \alpha \cdot w^K$.

**Lemma (I).** Let $\alpha_1 : K \to A_n$ $\alpha_2 : K \to A_k$. Then $\alpha_1 \oplus \alpha_2 = w_2^K \cdot (\alpha_2 \oplus \alpha_1) \cdot w_1^K$, where $w_1 \in GL_{n+k}$ is defined by $w_1(e_i) = e_{i+k}$ for $i \leq n$, $w_1(e_i) = e_{i-n}$ for $i > n$; $(e_1, ..., e_n, e_k)$ canonical basis for $R^{n+k}$ and $w_2 = w_1^{-1}$.

**Proof.** By direct substitution in equation defining $\oplus$. A direct computation shows $\det w > 0$ iff $n \cdot k = 0 (\text{mod } 2)$. Thus

**Corollary (I).** If $nk = 0 \pmod{2}$ then $\alpha_1 \oplus \alpha_2 \sim \alpha_2 \oplus \alpha_1$.

Let $t \in GL_{k+n}$ be defined by $t(e_i) = e_i$ for $i > 1$, $t(e_1) = -e_1$. Let $i = i|k^t$, $k^t \leq k^t \times R^n = R^{k+n}$. Using notation of Lemma (I).

**Corollary (II).** If $nk = 1 (\text{mod } 2)$ then $\alpha_1 \oplus \alpha_2 \sim tK \cdot (\alpha_2 \oplus \alpha_1) \cdot tK = (iK \cdot \alpha_2 \cdot iK \oplus \alpha_1)$.

Since $tK = e_k \cdot iK = e_k$ for any $k$, we have combining Corollary (I, II).

**Corollary (III).** For any $k$

$$
e_k \bar{K} \oplus \alpha_1 \sim \alpha_1 \oplus e_k \bar{K}.
$$

Combining Corollary (I, II, III).

**Corollary (IV).** $\alpha_1 \oplus \alpha_2 \oplus e_1 \bar{K} \sim \alpha_2 \oplus \alpha_1 \oplus e_1 \bar{K}$.

**Proof.** If $nk = 0 \pmod{2}$ this follows from Corollary (I). If $nk = 1 \pmod{2}$ we have

$$
\begin{align*}
\alpha_1 \oplus (\alpha_2 \oplus e_1 \bar{K}) &\sim (\alpha_2 \oplus e_1 \bar{K}) \oplus \alpha_1 &\sim &\alpha_2 \oplus \alpha_1 \oplus e_1 \bar{K}.
\end{align*}
$$
Consider the diagram

\[
\begin{array}{ccc}
A_m \times A_k & \overset{\oplus}{\rightarrow} & A_{m+k} \\
\downarrow i_r \downarrow i_s & & \downarrow i_{r+s} \\
A_{n+r} \times A_{k+s} & \overset{\oplus}{\rightarrow} & A_{n+k+r+s}
\end{array}
\]

with \( i_s(x) = x \oplus e_s x \).

This is not commutative, however, if \( \alpha_1 : K \rightarrow A, \alpha_2 : K \rightarrow A \) then \( i_r \alpha_1 = \alpha_1 \oplus e_r K, i_s \alpha_2 = \alpha_2 \oplus e_s K \). And

\[
i_r \alpha_1 \oplus i_s \alpha_2 = (\alpha_1 \oplus e_r K \oplus \alpha_2 \oplus e_s K) \sim (\alpha_1 \oplus \alpha_2 \oplus e_r K \oplus e_s K) = \alpha_1 \oplus \alpha_2 \oplus e_{r+s} K
\]

while \( i_{r+s} (\alpha_1 \oplus \alpha_2) = \alpha_1 \oplus \alpha_2 \oplus e_{r+s} K \).

**Corollary (V).** Thus applying the functor \([K, \ldots]\) one gets a commutative diagram

\[
\begin{array}{ccc}
[K, A_n] \times [K, A_\ell] & \overset{\oplus}{\rightarrow} & [K, A_{n+k}] \\
\downarrow i_{r+*} \downarrow i_{s+*} & & \downarrow i_{r+s+*} \\
[K, A_{n+r}] \times [K, A_{k+s}] & \overset{\oplus}{\rightarrow} & [K, A_{n+k+r+s}]
\end{array}
\]

The family \((A_1, i_s)\) is a directed system of complexes. Define

\[
A = \lim_{i} A_i.
\]

We call a complex \( K \) finite if it has only a finite number of non-degenerate simplicies. For any finite complex \( K \) an easy argument shows \([K, A] = \lim_{i} [K, A_i]\). It immediately follows that this is true for any complex \( K \) of the same homotopy type as a finite complex. Such a complex will be said to be of finite homotopy type. By Corollary (IV, V) and above remark we have

**Theorem (4.1).** The Whitney sum induces on \([K, A]\) for any finite homotopy type complex \( K \), the structure of an associative abelian monoid with two sided identity.

We will see that the restriction that \( K \) be finite is unnecessary and that \([K, A]\) is actually a group. We first consider the case \( A = O, PL \). Then \( A \) is actually a group under composition inherited from \( O_n, PL \). We will see that the above operation comes from the group structure.

Let \( \bar{\alpha}_1, \bar{\alpha}_2 \in [K, A], \) \( K \) finite. Let \( \alpha_1 \in [K, A_n], \alpha_2 \in [K, A_n] \) represent \( \bar{\alpha}_1, \bar{\alpha}_2 \). Then by Corollary (III), \( \alpha_1 \oplus e_r K \) and \( e_r K \oplus \alpha_2 \) also represent \( \bar{\alpha}_1, \bar{\alpha}_2 \). Then \( \bar{\alpha}_1 \cdot \bar{\alpha}_2 \) is represented by \( (\alpha_1 \oplus e_r K) \cdot (e_r K \oplus \alpha_2) = \alpha_1 \oplus \alpha_2 \). Thus the two operations in \([K, A]\) agree.

**Corollary (VII).** For \( A = O, PL \) the Whitney sum on \([K, A]\) is induced from group multiplication and thus extends to arbitrary \( K \). Further \([K, A]\) is an abelian group.

Since \( PL \rightarrow PD \) is a homotopy equivalence, the conclusion of Corollary (VII) applies to \([K, PD]\).
The following results on $PD/O$ make use of some deeper information. The only use we make of them in the sequel is of Theorem (4.2) for complexes $K$ of finite homotopy type, the proof of which for this case does not depend on any of the following assumptions.

**Assumption (A).** $\Gamma_n$ is finite for all $n \geq 0$.

A proof for the only doubtful case $\Gamma_4$ has been announced by Cerf but has not appeared. The other cases are dealt with in [8] and [3].

**Assumption (B).** $\gamma_0(PD/O) = \Gamma_n$.

This will be proved in the sequel.

For any complex $K$, let $K_n$ be the subcomplex generated by the $n$ section of $K$. A complex $K$ is called finite dimensional if $K = K_n$ for some $n$.

**Proposition (I).** Let $K$ be finite dimensional. Then there is a $j$ such that $i^* : [K, PD_j/O_j] \to [K, PD/O]$ is onto.

**Proof.** Let $M$ be a minimal subcomplex of $PD/O$ [7]. Then since $\gamma_n(PD/O)$ is finite for all $n$, $M_n$ is finite for all $n$. Then $M_n \to PD/O$ factors back $M_n \to PD_j/O_j$ up to homotopy. If $K$ is finite dimensional, $\alpha \in [K, PD/O]$ comes from $\alpha' \in [K, M_n]$ for some $n$. Thus since diagram

\[
\begin{array}{c}
& [K, PD/O] \ar[u] &
\end{array}
\]

commutes, the proposition follows.

**Corollary (VIII).** If $K$ is finite dimension, $[K, PD/O] = \lim_{i} [K, PD_j/O_j]$. Thus the Whitney sum operation extends to finite dimensional $K$.

**Proof is easy from above proposition.**

**Remark.** The following diagram

\[
\begin{array}{c}
[K, PD_n/O_n] \times [K, PD_k/O_k] \ar[r]^{\oplus} \ar[d]^{\xi} & [K, PD_{n+k}/O_{n+k}] \\
[K, BO_n] \times [K, BO_k] \ar[r]^{\oplus} & [K, BO_{n+k}] \ar[d]^{\xi}
\end{array}
\]

commutes, where $\oplus$ on the bottom denotes the Whitney sum of bundles. The proof comes from defining the Whitney sum of bundles through co-ordinate functions.

**Theorem (4.2).** For any finite dimensional complex $K$ the sequence

\[
[K, O] \xrightarrow{\mu} [K, PD] \xrightarrow{\lambda} [K, PD/O] \xrightarrow{\iota} [K, BO] \xrightarrow{\rho} [K, BPL]
\]

is an exact sequence of abelian groups.
**Proof.** That this is an exact sequence of basepointed sets is the usual property of fiber spaces applied to the fiber spaces

I \[ O \to PD \to PD/O \]
II \[ PD/O \to BO \to BPL \]

noticing that I is fibrations induced from II by inclusions \( PD/O \to BO \).

That the maps are additive follows from definitions; [The fact that \( \rho(\xi_1 \oplus \xi_2) = \rho(\xi_1) \oplus \rho(\xi_2) \), where \( \oplus \) denotes usual Whitney sum, follows from uniqueness of triangulation Theorem (3.1)]; and from above remark.

That \([K, BO]\) and \([K, BPL]\) are abelian groups is known. It only remains then to show that \([K, PD/O]\) is actually a group, i.e. that inverses exist. Let \( \alpha \in [K, PD/O] \) then \( \zeta[\alpha] \in [K, BO] \) has an inverse \( \nu \in [K, BO] \) since \( \rho \) is a group homomorphism \( \rho(\nu) = 0 \).

Thus there is an \( \alpha' \in [K, PD/O] \) with \( \zeta(\alpha') = v \). Thus \( \zeta(\alpha \oplus \alpha') = 0 \) or there is a \( \beta \in [K, PD] \) with \( \lambda(\beta) = \alpha \oplus \alpha' \). Now \( \beta \) has a negative in \([K, PD]\) so that \( \lambda(-\beta) + (\alpha + \alpha') = \lambda(\beta + -\beta) = 0 \). Thus \( \alpha' + \lambda(-\beta) \) is an inverse to \( \alpha \). Q.E.D.

**Theorem (4.3).** \( PD/O \) can be given the structure of an H-space such that for each finite dimensional \( K \), the Whitney sum on \([K, PD/O]\) comes from this H-space structure on \( PD/O \).

**Proof.** Let \( M \) be a minimal subcomplex of \( PD/O \). Then there exists a deformation retraction \( r: PD/O \to M \). As noted previously, the Whitney sum is defined on \([M_n \times M_n, PD/O] \times [M_n \times M_n, PD/O] \to [M_n \times M_n, PD/O] \).

Let \( \pi_i: M_n \times M_n \to PD/O, i = 1, 2, \) be projections and let \( \alpha \) represent \( \pi_1 \oplus \pi_2 \in [M_n \times M_n, PD/O] \). Then \( \alpha_{n+1}|M_n \times M_n \sim \alpha_n \). By homotopy extension theorem [7] ((\( PD/O \) is a Kan complex)), we can choose \( \alpha_{n+1} \) with \( \alpha_{n+1}|M_n \times M_n = \alpha_n \). Choosing inductively in this manner we have an \( \alpha: M \times M \to PD/O \). The retraction of \( PD/O \to M \) turns \( PD/O \) into an H-space with desired properties. Q.E.D.

**PART II—BUNDLES AND SMOOTHING THEORY**

§5. TUBULAR NEIGHBORHOOD THEOREM

**Theorem (5.1).** Given \( K \times R^k \to K \times R^k \) p.l. homeomorphism, \( \alpha|K \times O = \text{identity} \), \( K \) unbounded combinatorial manifold. Then

\[ \alpha \times 1_n: K \times R^k \times R^n \to K \times R^k \times R^n, \]

\( n \) sufficiently large, is isotopic to a fibrewise map relative to \( K \times O \).

The proof will be preceded by some definitions:

Let \( K \) be a complex. Let \( H_n(K) \) be set of germs of p.l. imbeddings \( \alpha: K \times R^n \to K \times R^n \) with \( \alpha|K \times O = \text{identity} \). We will denote by \( \alpha_2 \) the composite

\[ K \times R^n \to K \times R^n \to R^n. \]
Since $K$ is countable and locally finite, the set of simplicial maps $K \to PL_n, PL_n^K$, is in 1-1 correspondence with the set of germs of p.l. imbeddings $r : K \times R^n \to K \times R^n$ with $\gamma|K \times O = \text{identity}$, and $\pi_1(\gamma(k, y)) = k$. Thus there is an injection $PL_n^K \to H_n(K)$ and we henceforth consider $P_n^\ast \subseteq H_n(K)$.

Let $\alpha$ represent an element of $H_n(K)$, $\gamma$ an element of $PL_n^K$. Define $\alpha \oplus \gamma : K \times R^n \times R^n \to K \times R^n \times R^n$ by $\alpha \oplus \gamma : (k, x, y) = (\alpha(k, x), \gamma_2(k, y))$. If $1_n : K \times R^n \to K \times R^n$ then $\alpha \oplus \gamma = \text{composition} (1_n \oplus \gamma)(\alpha \oplus 1_n)$, and thus is an imbedding. Hence Whitney sum induces a pairing:

$$H_n(K) \times PL_n^K \rightarrow H_{n+r}(K).$$

Note that if $\gamma, \rho$ represent elements in $PL_n^K, PL_n^K : \oplus$ is the Whitney sum defined in I, 4 and that $$\alpha \oplus (\gamma \oplus \rho) = (\alpha \oplus \gamma) \oplus \rho.$$

Let $\alpha, \alpha'$ represent elements of $H_n(K)$. Define $\alpha \equiv \alpha'$ if there is a $t$ representing an element of $H_n(I \times K)$ such that $t|0 \times K \times R^n = \alpha$, $t|1 \times K \times R^n = \alpha'$. It is not difficult to see that if $\alpha, \alpha'$ have the same germ, $\alpha \equiv \alpha'$, so that the relation induces an equivalence relation in $H_n(K)$, still denoted by $\equiv$. It is clear that if $\tilde{\gamma}, \tilde{\gamma}'$ are homotopic elements of $PL_n^K$ that $\tilde{\gamma} \equiv \tilde{\gamma}'$ and further that if $\tilde{a}, \tilde{a} \in H_n(K), \tilde{a} \equiv \tilde{a}$' then $\tilde{a} \oplus \tilde{\gamma} = \tilde{a}' \oplus \tilde{\gamma}'$.

Finally, define for $\tilde{a} \in H_n(K), \tilde{a} \in H_n(K), \tilde{a} \equiv \tilde{a}$ if there exist integers $j, l$ with $\tilde{a} \oplus 1_j \equiv \tilde{a} \oplus 1_l$. It then follows that the equivalence classes in $H(K) = \bigcup_{n=0}^{\infty} H^n(K)$ under relation $\equiv$ are acted on by elements of $[K, PL]$ (homotopy classes of simplicial maps).

We also make use of the property that if $\tilde{a} \equiv \tilde{a}'$, then $\tilde{a} \equiv \tilde{a}'; \tilde{a}, \tilde{a}, t \in H_n(K)$.

**LEMMA.** For $\tilde{a} \in H_n(K), \tilde{\gamma} \in PL_n^K, \tilde{\gamma} \equiv \tilde{a} \oplus \tilde{\gamma}$.

**Proof.** Letting $\alpha, \gamma$ represent $\tilde{a}, \tilde{\gamma}$, we have $\alpha \oplus \gamma = (1_n \oplus \gamma)(\alpha \oplus 1_n)$. By Corollary III, p. 23, $1_n \oplus \gamma = \gamma \oplus 1_n$ in $[K, PL]$. Thus $(1_n \oplus \gamma)(\alpha \oplus 1_n) \equiv (\gamma \oplus 1_n)(\alpha \oplus 1_n) = (\gamma \alpha \oplus 1_n) \equiv \gamma \alpha$. Q.E.D.

We can now restate Theorem (5.1) in the following form.

Theorem (A). *Let $K$ be an unbounded combinatorial manifold. Then for each $\tilde{a} \in H_n(K)$ there exists a $\tilde{\gamma} \in PL_n^K$ with $\tilde{a} \equiv \tilde{\gamma}$.**

The proof depends on an intermediate construction. For the time being we assume $K$ is an arbitrary complex.

Let $\alpha$ represent an element of $H_n(K)$. Let $I = (-1/3, 4/3)$. Let $w^n$ be the identification space of $I \times K \times R^n$ under identification of $(1 + t, k, x)$ with $(t, \alpha(k, x))$, $-1/3 < t < 1/3$. And $P_n : I \times K \times R^n \rightarrow w^n$ the natural projection. Note $P_n$ is a local homeomorphism and
MICROBUNDLES AND SMOOTHING

$P_0(I \times K \times O) = S' \times K \subseteq w^a$. Further, if $\alpha$ represents an element in $PL_n^K$, $w^a$ is a microbundle over $S' \times K$.

Define $w^a \equiv w^a'$ if there is a p.l. homeomorphism $h$ of a neighborhood of $S' \times K$ in $w^a$ onto a neighborhood of $S' \times K$ in $w^a'$ with $h|S' \times K = \text{identity}$.

Finally it is straightforward to see that $w^a \equiv w^a' \Rightarrow \alpha \equiv \alpha'$.

**Proposition (I).** Let $\gamma, \gamma'$ represent elements of $H_\pi(K), \gamma$ an element of $PL_n^K$. If $\gamma \equiv \gamma'$ then $\gamma \cup \gamma$ is trivial.

**Proof.** First note commutative diagram

\[ I \times K \times R^n \xrightarrow{id \times 0} I \times K \times R^n \xrightarrow{\pi} I \times K \times R^n \]

Since $P_x, L_x \gamma$ are local homeomorphisms, $w^a \gamma$ is an $r$-dimension microbundle over $w^a$. The restriction of this bundle to $S' \times K$ is clearly $w^a$. Since $x \sim 1_x$ modulo $K \times O$, it is easily seen that inclusion $S' \times K \to W^a$ is a homotopy equivalence for $W^{1n} = S' \times K \times R^n$. Thus $W^{a \gamma}$ considered as a microbundle over $W^a$ is uniquely determined by its restriction to $S' \times K$. Now let $S' \times K \subseteq N^a \subseteq W^a$. Then $\lambda_2^{-1}(N^a) = W^{a \gamma|N^a}$ is a neighborhood of $\lambda_1(N^a) \subseteq W^{a \gamma|N^a}$. Given an $\alpha'$ representing an element of $H_n(K), \alpha'$ a neighborhood of $S' \times K \subseteq W^a$, a homeomorphism $h : N^a \to N^a'$ with $h|S' \times K = \text{identity}$; it follows that $W^a \gamma|N^a$ is equivalent as a microbundle over $N^a$ to $h^*(W^a \gamma|N^a)$. Thus there is a homeomorphism $h$ of a neighborhood of $\lambda_1(N^a) \subseteq W^a \gamma|N^a$ onto a neighborhood of $\lambda_1(N^a) \subseteq W^{a \gamma|N^a}$ with $h \lambda_1 = \lambda_1 h$. Since $h|S' \times K = \text{identity}$, $\lambda_1|S' \times K = \text{identity}$ and thus $W^{a \gamma} \equiv W^{a \gamma}$.

**Proposition (II).** Let $\alpha$ represent an element of $H_n(K)$ and suppose $W^a \equiv W^{1n}$. Then $\alpha \equiv 1_n \equiv 1_{n+1}$.

**Proof.** Since we can retract by a homeomorphism $W^{1n} = S' \times K \times R^n \to$ into any neighborhood of $S' \times K \times O$ leaving a smaller neighborhood fixed we may as well assume the equivalence between $W^{1n}$ and $W^a$ is given by an embedding $h : S' \times K \times R^n \to W^a$. We further can assume $h$ has the following properties:

1. $hP_{n}((-1/4, 1/4) \times K \times R^n) \subseteq P_a((-1/3, 1/3) \times K \times R^n)$
2. $hP_{n}((3/4, 5/4) \times K \times R^n) \subseteq P_a((2/3, 4/3) \times K \times R^n)$

Then one can cover $h$, by a map $\tilde{h}$ so that the following diagram commutes.

\[ \begin{array}{ccc}
(-1/4, 5/4) \times K \times R^n & \xrightarrow{\tilde{h}} & I \times K \times R^n \\
\downarrow & & \downarrow \\
S' \times K \times R^n & \xrightarrow{h} & W^a
\end{array} \]
$h$ is uniquely determined by this and the fact that $h(t, k, O) = (t, k, O) \in (1/4, 5/4)$. Clearly $h$ is an imbedding.

Now let $Q_1 = h((-1/4, 1/4) \times K \times R^n)$, $Q_2 = h((3/4, 5/4) \times K \times R^n)$. Then we must have $Q_2 = Q_1$ on $(-1/4, 1/4) \times K \times R^n$. Now let $\rho$ be a $p.f.$ homeomorphism $\rho: R \to (-1/4, 1/4)$ with $\rho((-1/8, 1/8)) = \text{identity}$. Let $\bar{\rho}: K \times R^n \times R \to (-1/4, 1/4) \times K \times R^n$ by $\bar{\rho}(k, x, y) = (\rho(y), k, x)$. Also let

$$
\sigma: I \times K \times R^n \xrightarrow{\text{id} \times \text{inclusion}} K \times R^n \times I \xrightarrow{\text{permute}} K \times R^n \times R.
$$

Then $\sigma(1 \times \alpha)Q_2 \rho = \sigma Q_1 \rho$ as maps $K \times R^{n+1} \to K \times R^{n+1}$. Notice that they represent elements of $H_{n+1}(K)$. Consider the map $H: I \times K \times R^n \times R \to I \times K \times R^n \times R$ defined as composite of the following

$$
I \times K \times R^n \xrightarrow{\text{permute}} I \times (-1/3, 4/3) \times K \times R^n \xrightarrow{\text{id} \times \text{Inclusion}} I \times K \times R^n \times (-1/3, 4/3) \to I \times K \times R^n \times R,
$$

where $h(t, t', k, y) = t, h(t + t', k, y)$. Then $H$ represents an element of $H_{n+1}(I \times K)$ and $H_0 = \sigma Q_1 \bar{\rho}, H_1 = \sigma Q_2 \bar{\rho}$. Hence

$$
\sigma Q_1 \bar{\rho} = \sigma Q_2 \bar{\rho} \text{ and thus } \sigma(1 \times \alpha)Q_2 \bar{\rho} = \gamma Q_2 \bar{\rho} \text{ and thus } \sigma(1 \times \alpha)\sigma^{-1} = 1_{n+1} \text{ where the left hand side is well defined on } K \times R^n \times (-1/3, 4/3) \text{ and thus represents an element of } H_{n+1}(K) \text{. Since } \sigma(1 \times \alpha)\sigma^{-1} \text{ has the same germ as } \alpha \oplus 1_{1}, \text{ the proof is complete.}
$$

**Corollary to Proposition (II, I).** Let $\alpha$ represent an element of $H_{n}(K), \gamma$ and element of $\text{PL}_{K}$. If $W^n \oplus 1_s \equiv W^n \oplus 1_s$, then $\alpha \equiv \gamma$.

**Proof.** $W^n \oplus 1_s \equiv W^n \oplus 1_s \Rightarrow W^n \oplus 1_s \oplus \gamma^{-1} \equiv W^n \oplus 1_s \oplus \gamma^{-1} \equiv W^n \oplus \gamma^{-1} \oplus 1_s = W^{1+s}_{1+s}$. Then by Proposition (II) $\alpha \oplus 1_s \oplus \gamma^{-1} \equiv 1_{2s+t}$ or $\alpha \equiv \gamma$. Q.E.D.

**Proposition (III).** Let $\alpha$ represent an element of $H_{n}(K)$ where $K$ is an unbounded combinatorial manifold. Then for $r$ sufficiently large there exists a $\gamma$ representing an element of $\text{PL}_{n+r}$ with $W^n \oplus 1_s \equiv W^n.$

**Proof.** $W^n \oplus 1_s$ is also an unbounded combinatorial manifold. Without loss of generality we may assume $W^n \oplus 1_s$ is orientable [for if not, choose $\gamma$ representing an element of $\text{PL}_{n} \oplus 1_s$ with the first Stiefel–Whitney class $\neq 0$ as microbundle over $S' \times K$. The normal bundle of $W^n \oplus 1_s$ in $W^n \oplus 1_s$ has the first Stiefel–Whitney class $\neq 0$ as in proof of Proposition (I). Thus if $W^n \oplus 1_s$ is non orientable, $W^n \oplus 1_s$ is orientable and thus we can work with $\alpha + \gamma$. Now choose $r$ so large that $S' \times K$ has a normal bundle in $W^n \oplus 1_s \equiv W^n \oplus R'$. Call bundle $\varepsilon^{n+s}$. Since $W^n \oplus 1_s$ is orientable $\varepsilon^{n+s} \times k, k \in K$ is trivial (See Lemma (10), Milnor [4]). By construction of $W^n \oplus 1_s, \varepsilon^{n+s} \times K, p \in S'$ is trivial.

Thus classifying map $S' \times K \to \text{BPL}_{n+r}$ factors through $S' \times K \to S' \wedge K \to \text{BPL}_{n+r}$. The homotopy class of $\varepsilon'$ is determined by a characteristic map $\gamma: K \to \text{PL}_{n+r}$. And clearly
MICROBUNDLES AND SMOOTHING

\( W^\varepsilon \equiv \varepsilon_{n+r} \) as a bundle over \( S' \times K \). Since \( \varepsilon \) is a normal bundle for \( S' \times K \) in \( W^{n+1}_r \), \( W^r \equiv W^{n+1}_r \) and proposition follows.

Theorem (A) follows immediately from Corollary and Proposition (III) as does:

**Theorem (B).** \( \varepsilon \equiv \varepsilon' \) if and only if \( W^{n+1}_r \equiv W^{n+1}_r \). For some \( s, r, \) where \( \varepsilon \) represents an element of \( H_n(K) \), \( \varepsilon' \) an element of \( H_n(K) \), \( K \) an unbounded combinatorial manifold.

**Query.** Are Theorem (A) or the Weaker Theorem (B) true for arbitrary complexes \( K \)? It seems quite likely, yet the proof may be difficult.

**Theorem (5.2).** Let \( \mu, v \) be p.l. microbundles over a combinatorial manifold \( K \), and let \( f : E(\mu) \rightarrow E(v) \) be a zero-preserving p.l. homeomorphism. Then for \( s \) sufficiently large

\[
F \times 1_s : E(\mu) \times R^s \longrightarrow E(v) \times R^s
\]

is p.l. isotopic, relative to the zero-section, to a fibrewise map.

**Proof.** 1. Let \( \lambda \) be any microbundle over \( K \), and \( \lambda' \) any inverse to \( \lambda \). Let \( \pi_\mu, \pi_v \) be the bundle projections in \( \mu, v \) respectively. Now \( E(f^* \pi^*_v \lambda) = \{ (x, y) \in E(\mu) \times E(\pi^*_v \lambda) | f(x) = \rho(y) \} \), \( \rho \) the projection \( E(\pi^*_v \lambda) \rightarrow E(\lambda) \). Consequently, we have the natural bundle map \( \varphi_\lambda : E(f^* \pi^*_v \lambda) \rightarrow E(\pi^*_v \lambda \otimes \lambda') \), \( \varphi_\lambda(x, y) = y \). Similarly, we have \( \varphi_{\lambda'} : E(f^* \pi^*_v \lambda') \rightarrow E(\pi^*_v \lambda \otimes \lambda') \), and finally \( \varphi_{\lambda \oplus \lambda'} : E(f^* \pi^*_v \lambda \otimes \lambda') \rightarrow (\pi^*_v \lambda \otimes \lambda') \). Then

\[
\begin{array}{c}
E(f^* \pi^*_v \lambda \otimes f^* \pi^*_v \lambda') \\
\downarrow \varphi_{\lambda \oplus \lambda'} \\
E(\pi^*_v \lambda \otimes \lambda') \\
\downarrow f \times 1_s \\
E(\mu) \times R^s \\
\end{array}
\]

\[
\begin{array}{c}
E(f^* \pi^*_v \lambda \otimes \lambda') \\
\downarrow \varphi_\lambda \oplus \varphi_{\lambda'} \\
E(\pi^*_v \lambda \otimes \lambda') \\
\downarrow f \times 1_s \\
E(\mu) \times R^s \\
\end{array}
\]

commute under the natural equivalence. \( s = \dim \lambda \times \dim \lambda' \).

2. Since we may assume \( K \) is a p.l. deformation retract of \( E(\mu) \), \( f^* \pi^*_v \lambda \cong \pi^*_v \lambda \). Since \( E(\pi^* \lambda) = E(\nu \oplus \lambda) \) and \( E(\pi^*_v \lambda) = E(\mu \oplus \lambda) \), \( \varphi_\lambda \) corresponds under identifications to a zero-preserving map \( g : E(\mu \oplus \lambda) \rightarrow E(\nu \oplus \lambda) \).

Similarly, \( \varphi_{\lambda'} + \varphi_{\lambda'} \) corresponds to a bundle map

\[
h : E(\pi^*_v \lambda \oplus \lambda') \rightarrow E(\pi^*_v \lambda + \lambda') \text{ covering } g.
\]

Suppose \( g \) is isotopic to a fibrewise map, relative to the zero-sections. This isotopy may be covered by a bundle isotopy of \( h \), to a fibrewise map as bundles over \( K \). But then \( \varphi_\lambda \oplus \varphi_{\lambda'} \) and hence by (1), \( f \times 1_s \), is isotopic to a fibrewise map as bundles over \( K \), relative to zero-sections.

3. Since by uniqueness of stable normal bundles, \( \mu \cong v \), we can take \( \lambda \) to be an inverse of both \( \mu \) and \( v \). Then \( g : E(\mu \oplus \lambda) \rightarrow E(\nu \oplus \lambda) \) may be considered a zero-preserving map \( K \times R^n \rightarrow K \times R^n \), \( n = \dim \lambda \). Since we may always add a trivial bundle to \( \lambda \), Theorem (5.1) implies \( g \) is isotopic to a fibrewise map for \( n \) sufficiently large; and Theorem (5.2) follows from the argument (2) above.
Theorem (5.3). Let \( f_i : K \to V, i = 0, 1, \) be p.l. imbeddings, where \( K \) and \( V \) are combinatorial manifolds without boundary, then

(a) \( f_i(K) \) has a normal microbundle \( \mu_i \) in \( V \times R^n, n \) sufficiently large; i.e. there exists p.l. homeomorphisms \( F_i : E(\mu_i) \to V \times R^n \) such that \( F_i \) restricted to the zero-section is \( f_i : K \to V \times 0. \)

(b) If \( h : K \times I \to V \times I \) is any p.l. isotopy between \( f_0 \) and \( f_1 \), there exists a p.l. isotopy \( H : E(\mu_0) \times R^k \times I \to V \times R^{n+k} \times I, k \) sufficiently large, covering \( h \), and such that \( H_0 = F_0 \times 1_k, H_1 \) is a microbundle equivalence of \( E(\mu_0) \times R^k \) into \( F_1(E(\mu_1)) \times R^k. \)

(b) Extend \( h \) to a p.l. imbedding \( \tilde{h} : K \times R \to V \times R, \) by setting

\[
\tilde{h}(x, t) = (f_0(x), t), t < 0
\]
\[
= h(x, t), 0 \leq t \leq 1
\]
\[
= (f_1(x), t), t > 1
\]

Then \( \tilde{h}(K \times R) \) has a normal microbundle in \( V \times R \times R^{n+k}, k \) sufficiently large. By the covering homotopy Theorem [5], this bundle is of the form \( v \oplus 1 \), where \( v \) is a bundle over \( K \), i.e. there exists a p.l. homeomorphism \( G : E(v) \times R \to V \times R \times R^{n+k}, G|K \times R = \tilde{h} \) (but not necessarily commuting with projection into \( R \)).

Now \( G \) may not be an isotopy, but \( \Gamma : E(v) \times R \times I \to V \times R \times R^{n+k} \times I, \) defined by \( \Gamma(x, s, t) = (G(x, s + t), t) \) is a p.l. isotopy, for any interval \( I. \)

On the other hand, we claim that \( F_0 \times 1_{k+1} : E(\mu_0) \times R^{k+1} \to V \times R^{n+k+1} \) is p.l. isotopic, relative to the zero-section, to a fibrewise map \( F_0 \) w.r.t. \( \Gamma_0 = \Gamma|E(v) \times R \times (O); \) i.e.

\[
\begin{array}{ccc}
E(\mu_0) \times R^{k+1} & \xrightarrow{F_0} & V \times R^{n+k+1} \\
\phi \downarrow & & \downarrow \phi \\
E(v) \times R & \xrightarrow{F_0} & \\
\end{array}
\]

where \( \phi \) is a microbundle equivalence.

In fact, \( F_0 \times 1_{k+1} \) and say \( \Gamma_{-1} \) may both be thought of as normal microbundles of \( f_0(K) = \Gamma_{-1}(K \times 0) \subset V \times (-1) \times 0 \subset V \times R \times R^{n+k}. \) Hence \( F_i \times 1_{k+1} \) is isotopic relative to \( K \) (by Theorem (5.2)) to a fibrewise map w.r.t. \( \Gamma_{-1}; \) But \( \Gamma_{-1}, \Gamma_0 : E(v) \times R \to V \times R^{n+k+1} \) are isotopic, relative to \( K \).

Similarly, \( \Gamma_1 \) is isotopic to say \( \Gamma_2, \) which in turn is isotopic to a fibrewise map w.r.t \( F_1 \times 1_{k+1}. \) Since \( \Gamma_0 \) is also p.l. isotopic to \( \Gamma_1, \) we may combine these isotopies to give a p.l. isotopy \( H : E(\mu_0) \times R^{k+1} \times I \to V \times R^{n+k+1} \times I \) such that \( H_0 = F_0 \times 1_{k+1} \) and \( H_1 \) is fibrewise w.r.t. \( F_1 \times 1_{k+1}. \) Hence for \( k \) sufficiently large (i.e. writing \( k \) for \( k + 1 \)), we get conclusion (b), and the Theorem is proved.
§6. SMOOTHING COMBINATORIAL MANIFOLDS

DEFINITION (6.1). Let $K$ be a combinatorial $n$-manifold. A smoothing of $K$ is a pair $(M, f)$, where $M$ is a smooth $n$-manifold and $f : K \to M$ is a non-singular p.d. homeomorphism.

Two smoothings $(M_1, f_1)$ and $(M_2, f_2)$ are called equivalent if there exists a diffeomorphism $d : M_1 \to M_2$ such that

\[
\begin{array}{ccc}
K & \xrightarrow{f_1} & M_1 \\
\downarrow{f_2} & & \downarrow{d} \\
M_2 & \xrightarrow{d} & M_1
\end{array}
\]

commute.

DEFINITION (6.2). Two smoothings $(M_1, f_1), (M_2, f_2)$ of a combinatorial manifold $K$, without boundary, are called concordant, if there exists a smoothing $(W, F)$ of $K \times I$, $F : K \times I \to W$ such that $\partial W = \text{disjoint union of } M_1, M_2$ and $F_{|k \times 0} = f_1, F_{|k \times 1} = f_2$.

More explicitly, we are given diffeomorphisms $d_i : M_i \to W$, $i = 1, 2$, $d_i(M_i) \cap d_j(M_j) = \emptyset$, $d_1(M_1) \cup d_2(M_2) = \partial W$ and

\[
\begin{array}{ccc}
K & \xrightarrow{f_1} & M_1 \\
\downarrow{f_2} & & \downarrow{d_1} \\
K \times I & \xrightarrow{F} & W \\
\downarrow{i_0} & & \downarrow{i_1} \\
M_1 & \xrightarrow{d_i} & M_1 \\
\downarrow{d_1} & & \downarrow{d_2} \\
M_2 & \xrightarrow{d_2} & M_2
\end{array}
\]

commute.

In the remainder of the paper we deal only with combinatorial manifolds of the homotopy type of a finite complex. This will be understood in what follows.

The basic theorem of concordance theory is the Cairns–Hirsch [2] Theorem. We use it in the following form [4].

THEOREM—Cairns–Hirsch. Let $(f, M)$ be a smoothing of $K \times R^k$. Then there exists a smoothing $(g, N)$ of $K$, unique up to concordance with the following property.

There is a piecewise differentiable isotopy $H : K \times R^k \times I \to M \times I$ with $H_0 = f$, and $H_1 = \phi(g \times \text{id})$ where $\phi$ is an imbedding $\phi : N \times \times R^k \to M$.

DEFINITION (6.3). A trivial triangulation of a p.d. vector bundle $E^n$ over a locally finite complex $K$ is a triangulation $(1^n, \varphi)$, where $E(1^n) = K \times R^n$, $\varphi : K \times R^n \to E(\xi)$. We write $(\varphi, \xi)$ for a trivially triangulated p.d. bundle.

Two trivially triangulated p.d. bundles $(\varphi_1, \xi_1^1), (\varphi_2, \xi_2^2)$ over $K$ are called equivalent if there exists a trivially triangulated p.d. bundle $(\varphi, \xi)$ over $K \times I$ such that $\xi|K \times O \simeq \xi_1$, $\xi|K \times 1 \simeq \xi_2$, $\varphi|K \times O \times R^n \simeq \varphi_1$, $\varphi|K \times 1 \times R^n \simeq \varphi_2$.

More explicitly, there exists p.d. bundle equivalences

\[
\psi : E(\xi_1) \to E(\xi)|_{K \times 0}, \psi_2 : E(\xi_2) \to E(\xi)|_{K \times 1},
\]
such that

\[
\begin{align*}
K \times \mathbb{R}^n &\xrightarrow{\varphi_1} E(\xi_1) \quad & K \times \mathbb{R}^n &\xrightarrow{\varphi_2} E(\xi_2) \\
\downarrow i_0 & & \downarrow i_1 \\
K \times I \times \mathbb{R}^n &\xrightarrow{\varphi} E(\xi) & K \times I \times \mathbb{R}^n &\xrightarrow{\varphi} E(\xi)
\end{align*}
\]

commute.

**Alternative definition of equivalence**

More simply, if less symmetrically, there exists a p.d. bundle equivalence \(\psi : E(\xi_1) \to E(\xi_2)\) such that \(\psi \varphi_1\) is isotopic to \(\varphi_2\) through trivial triangulations.

Further, since the Whitney sum of a p.d. bundle and a trivial bundle has a naturally defined p.d. structure, we may define *stable equivalence* of trivially triangulated p.d. bundles over \(K\): \((\varphi_1, \xi_1), (\varphi_2, \xi_2)\) are called stably equivalent if there exists a trivially triangulated p.d. bundle \((\varphi, \xi')\) over \(K \times I\) such that \(\xi'|_{K \times O} \simeq \xi_1\), \(\xi'|_{K \times 1} \simeq \xi_2\), \(\varphi|^{|_{K \times O \times \mathbb{R}^n} \simeq \varphi_1\), \(\varphi|K \times 1 \times \mathbb{R}^n \simeq \varphi_2\).

We denote the set of stable equivalence classes of trivially triangulated p.d. bundles by \(T\). \(T\) is a set with unit element, namely the class of \((I, 1): I : K \times \mathbb{R}^n \to K \times \mathbb{R}^n\) the identity.

Let \(C = C(K)\) be the concordance classes of smoothings of a combinatorial manifold \(K\), and let \(c_0 \in C\) be a distinguished class. We will denote this set with distinguished class by \(C_0\).

Let \(\overline{K}\) be the s.s. complex corresponding to \(K\). Let \(O = \lim\) \(O_n\) be the direct limit of the s.s. complexes defined above. Let \([\overline{K}, O]\) be the s.s. homotopy classes of s.s. maps of \(\overline{K}\) into \(O\). Define \([\overline{K}, PD]\), \([\overline{K}, BO]\), \([\overline{K}, BPL]\) similarly. Let \(\mu : [\overline{K}, O] \to [\overline{K}, PD]\) be the map induced by the inclusion \(\mu : O \to PD\). Let \(p : BO \to BPL\) be induced by \(p : BO \to BPL\). Define an action of \([\overline{K}, PD]\) on \(C_0\) as follows: Let \((M, \eta) \in C_0\), and let \(g : K \times \mathbb{R}^n \to M \times \mathbb{R}^n\) represent a class \((g) \in [\overline{K}, PD]\). Let \(h : K \times \mathbb{R}^n \to M \times \mathbb{R}^n\) be the composition \(K \times \mathbb{R}^n \xrightarrow{g} K \times \mathbb{R}^n \xrightarrow{f \times 1} M \times \mathbb{R}^n\); then \(h\) is a non-singular p.d. homeomorphism. Let \(\{(M_1, f_1)\}\) be the concordance class defined from \(h\) by the Cairns-Hirsch theorem. This is clearly independent of the choice of \(g\). Further, it depends only on the concordance class \(c\); as is proved by applying the same construction to the given concordance. We denote this action by \(\lambda\). Now define a map \(\zeta : C_0 \to [KBO]\) by \(\zeta((M, f)) = \text{homotopy class of the stable classifying map for } \tau \oplus \tau_0^{-1}\), where \(\tau = \text{tangent bundle of } M\), \(\tau_0 = \text{tangent bundle } M_0\). It is clear, that this depends only on the concordance class of \((M, f)\), and \((M_0, f_0)\) since concordant manifolds are diffeomorphic [10], and hence have the same stable tangent bundles.

**Definition (6.4).** Let \(G, H, K, L\) be groups, and \(C\) a base-pointed set with \(H\) as a group of operators on \(C\). Let \(\lambda : C \times H \to C\) be the operation. Let \(\mu : G \to K\) a map of base-pointed
sets. Then we say that

\[ G \rightarrow H \rightarrow C \rightarrow K \rightarrow L \]

is exact if the following hold:

1. \( \lambda(h, c) = c \) if and only if \( h \in \mu(G) \).
2. \( \xi(c_1) = \xi(c_2) \) if and only if \( c_2 = \lambda(c_1, h) \) for some \( h \in H \).
3. \( \nu(k) = 1 \) if and only if \( k \in \xi(C) \).

Remark. If \( C \) is a group, then an exact sequence of groups \( G \rightarrow H \rightarrow C \rightarrow K \rightarrow L \) is an exact sequence in the above sense, where \( \lambda(c, h) = c\lambda(h) \).

5—Lemma. Let

\[
\begin{array}{ccccccc}
G_1 & \xrightarrow{\mu_1} & H_1 & \xrightarrow{\lambda_1} & C_1 & \xrightarrow{\zeta_1} & K_1 & \xrightarrow{\nu_1} & L_1 \\
\phi_1 & \downarrow & \phi_2 & \downarrow & \rho & \downarrow & \psi_1 & \downarrow & \psi_2 \\
G_2 & \xrightarrow{\mu_2} & H_2 & \xrightarrow{\lambda_2} & C_2 & \xrightarrow{\zeta_2} & K_2 & \xrightarrow{\nu_2} & L_2 \\
\end{array}
\]

be a commutative diagram, where the horizontal rows are exact in the sense of Definition (6.4), \( \phi_1, \phi_2, \psi_1, \psi_2 \) are group isomorphisms and \( \rho \) is a map of base-pointed sets with operators. Then \( \rho \) is an isomorphism of base-pointed sets with operators.

Proposition (6.1). \([\mathcal{K}, O]\xrightarrow{\mu} [\mathcal{K}, PD] \xrightarrow{\lambda} C_0 \xrightarrow{\xi} [\mathcal{K}, BO] \xrightarrow{\nu} [\mathcal{K}, BPL] \) is exact

Proof. 1. Order two

(a) \( \lambda \bar{\mu} \)

This is just Proposition (3.1) applied to the trivial bundle over \( M \), for using smoothing \( f : K \rightarrow M \), an element of \([\mathcal{K}, O]\) is exactly a p.d. vector bundle map \( M \times R^n \rightarrow M \times R^n \) and the isotopy given by proposition deforms this to a differentiable bundle map \( M \times R^n \rightarrow M \times R^n \).

(b) \( \xi \lambda \)

Let \( (g) \in [K, PD] \) and let \( h : K \times R^n \rightarrow M \times R^n \) be the induced p.d. homeomorphism. Then the Cairns–Hirsch theorem gives that \( h \) is a p.d. isotopic to a p.d. homeomorphism \( h_1 : K \times R^n \rightarrow M_1 \times R^n \rightarrow M \times R^n \), where \( d \) is a diffeomorphism. It follows that \( M_1 \) has the same stable tangent bundle as \( M \). Hence \( \xi \lambda((g), c) = K(c) \).

(c) \( \rho \xi \)

Since any two smoothings of \( K \) have tangent bundles with the same underlying tangent microbundle, and \( \bar{\rho} \) is a homomorphism w.r.t. Whitney sum; \( \bar{\rho}(c) \) — homotopy class of the classifying map for the trivial microbundle.

2. Exactness

(a) \([\mathcal{K}, PD] \)

Suppose \( (g) \in [\mathcal{K}, PD] \) is such that \( \lambda((g), c) = c \) for some \( c \in C_0 \). We wish to show that \( (g) \) comes from \([\mathcal{K}, O]\). Starting with \((M_1, f_1) \in c\), the action of \( (g) \) must lead by the construction \( \lambda \) to \((M_2, f_2) \in c\). Let \( f : K \times I \rightarrow V \) be the concordance between \((M_1, f_1)\) and
The imbedding (which we denote $d_2$) of $M_2 \times \mathbb{R}^n$ in $M_1 \times \mathbb{R}^n$ of the $\lambda$-construction, can be extended to a smooth imbedding $d : V \times \mathbb{R}^n \to M_1 \times I \times \mathbb{R}^n$, such that $d|M_2 \times \mathbb{R}^n = d_2 : M_2 \times \mathbb{R}^n \to M_1 \times O \times \mathbb{R}^n$ and $d|I \times \mathbb{R}^n = (1) \times \mathbb{R}^n$ is the identity. In fact, $V$ is diffeomorphic to $M_1 \times I$, and any two imbeddings of $M_1 \times \mathbb{R}^n$ are isotopic if $n$ is sufficiently large. Now $d^2 = (1) \times \mathbb{R}^n$ is $p.d.$ isotopic to a $p.l.$ imbedding $f : K \times I \times \mathbb{R}^n \to K \times I \times \mathbb{R}^n$, such that $f|K \times 1 \times \mathbb{R}^n$ is fibrewise $p.d.$ isotopic to $d^2 = (1) \times \mathbb{R}^n \in [K, O]$, and $f(K \times I \times \mathbb{R}^n) : K \times O \times \mathbb{R}^n \to K \times O \times \mathbb{R}^n$ is $g$. Now $f$ may be extended to a map $h : K \times R \times \mathbb{R}^n \to K \times R \times \mathbb{R}^n$, by extending the maps over the two boundaries of $K \times I$ in constant fashion. Since $h|K \times R \times O : K \times R \times O \to K \times R \times \mathbb{R}^n$ is isotopic to the identity, relative to $K \times (R - \text{Int } I)$, the Tubular Neighborhood Theorem gives a covering isotopy of $h$ to a fibrewise map. But this shows that $h|K \times 1 \times \mathbb{R}^n$ and $h|K \times O \times \mathbb{R}^n$ are stably isotopic in $PD$. Hence $g$ comes from $[\overline{K}, O]$.

(b) $C_0$

Let $(M_1, f_1), (M_2, f_2)$ represent two concordance classes $c_1, c_2$ respectively, such that $K(c_1) = K(c_2)$; i.e. $\tau_1 \simeq \tau_2$. Then there is a smooth imbedding $i : M_2 \times \mathbb{R}^n \to M_1 \times \mathbb{R}^n$; for $n$ sufficiently large; such that $i f_2 : K \to M_2 \times \mathbb{R}^n \to M_1 \times \mathbb{R}^n$ is homotopic to $f_1$, and hence $p.d.$ isotopic to $f_1$. By the tubular neighborhood theorem, $i f_2(1) \times \mathbb{R}^n$ is $p.d.$ isotopic to a $p.l.$ bundle map $g : K \times \mathbb{R}^n \to K \times \mathbb{R}^n$. Hence $c_2 = \lambda((g), c_1), (g) \in [\overline{K}, PD]$.

(c) $[\overline{K}, BO]$

Let $(h) \in [K, BO]$. Then if $\tilde{p}(h) = 0$, $(h)$ represents a $p.d.$ vector bundle $\xi$ which has a trivial triangulation $\varphi$. Then $\varphi : K \times \mathbb{R}^n \to \mathbb{E}(\xi), \mathbb{E}(\xi)$ the diff. vector bundle over $M_0$, defines a concordance class $c$, with tangent bundle $\xi$; i.e. $K(c) = (h)$.

Proposition (6.2). $[\overline{K}, O] \to [\overline{K}, PD] \to [\overline{K}, BO] \to [\overline{K}, BPL]$ is exact, where

1. Order two

(a) $\lambda \tilde{p}$

Let $(g) \in [\overline{K}, O], (\varphi, \xi) \in t \in T$. Then $\lambda((g), t)$ is the class of $\varphi \oplus g : K \times \mathbb{R}^n \times \mathbb{R}^m \to E(\xi) \times \mathbb{R}^m$, but $\varphi \oplus g = 1 \oplus g \oplus 1, 1 \oplus g : E(\xi) \times \mathbb{R}^m \to E(\xi) \times \mathbb{R}^m$. Since this last is a $p.d.$ bundle equivalence $(\varphi \oplus g, \varphi \oplus 1^m) \in t$.

(b) $\zeta \lambda$

$\zeta((\varphi \oplus f, \varphi \oplus 1^m) = \zeta((\varphi, \xi))$ by definition (see 2) above

(c) $\rho \zeta$

If $(\varphi, \xi) \in t \in T, \varphi$ by definition has a trivial triangulation, and $\tilde{p}(t)$ is the homotopy class of the classifying map for the trivial microbundle.

2. Exact

(a) $[\overline{K}, PD]$
Let \((g) \in [\tilde{K}, PD]\), \((\varphi, \xi) \in t \in T\); and suppose \(\lambda((g), t) = t\). Then after stabilizing, we have

\[
\begin{array}{c}
E(\xi) \times R^m \\
\downarrow \varphi \oplus g \\
K \times R^m \times R^n \\
\downarrow \psi \\
E(\xi) \times R^m
\end{array}
\]
commutes up to isotopy through trivial triangulations, where \(\psi\) is a p.d. bundle equivalence (see alternative definition of equivalent trivial triangulations). Hence \(\psi_0((\varphi \oplus 1)|K \times O \times R^m : K \times O \times R^m \to K \times R^m \subset E(\xi) \times R^m\) is isotopic in \(PD_m\) to \(\varphi \oplus g|K \times O \times R^m : K \times O \times R^m \to K \times R^m \subset E(\xi) \times R^m\). Identifying \(K \times O \times R^m\) with \(K \times R^m\), \(\varphi \oplus g|K \times O \times R^m = g\) and \(\psi_0((\varphi \oplus 1)|K \times O \times R^m = \psi|K \times R^m\). Hence \(g\) is isotopic in \(PD_m\) to \(\psi|K \times R^m\), where \((\psi|K \times R^m) \in [\tilde{K}, O]\).

(b) \(T\)

Let \((\varphi_1, \xi_1) \in t_1 \in T\), \(i = 1, 2\), and suppose that \(\zeta(t_1) = \zeta(t_2)\); i.e. \(\zeta_1 \approx \zeta_2\). Then we may suppose \(\zeta_1 = \zeta_2 = \zeta\), and \(\varphi_i : K \times R^n \to E(\xi),\ i = 1, 2\), are two triangulations. Then \(\varphi_2\) is isotopic through triangulations to

\[
\begin{array}{c}
\varphi_2' : K \times R^n \\
\downarrow \varphi_1 \\
K \times R^n
\end{array}
\]

homomorphism. I.E. \((g) \in [\tilde{K}, PD]\) and \(\lambda((g), t_1) = t_2\).

(c) \([\tilde{K}, BO]\)

Let \((h) \in [\tilde{K}, BO]\), and suppose \(\tilde{h}(h)\) is trivial. I.E. \((h)\) represents a p.d. bundle \(\xi\) which has a trivial triangulation \(\varphi\). Then \(\zeta\{(\varphi, \xi)\} = (h)\).

Result from previous section

\[
\begin{array}{c}
[\tilde{K}, O] \\
\tilde{\rho} \\
[\tilde{K}, PD] \\
\tilde{1} \\
[\tilde{K}, PD/O] \\
\tilde{\zeta} \\
[\tilde{K}, BO] \\
\tilde{\rho} \\
[\tilde{K}, BPL]
\end{array}
\]
is an exact sequence of groups.

Definition of \(\tilde{\rho} : T \to C_0\):

Let \(f_0 : K \times M_0\) be a given smoothing. Let \((\varphi, \xi)\) be a triangulated p.d. bundle, \(\varphi : K \times R^n \to E(\xi)\). Considering \(\xi\) as a vector bundle over \(M_0\), \(E(\xi)\) may be given a unique differential structure as a diff. vector bundle, up to diff. bundle equivalence. Denote \(E(\xi)\) with this diff. structure by \(\tilde{E}(\xi)\). Then there exists a p.d. bundle map \(\psi : \tilde{E}(\xi) \to \tilde{E}(\xi)\) over the map \(f_0 : K \to M_0\); i.e. \(\psi\) is diff. over each simplex of some rectilinear subdivision of \(K\). Then \(\psi \varphi : K \times R^m \to E(\xi)\) is a p.d. homeomorphism. By the Hirsch product theorem it defines a concordance class of smoothings of \(K\).
To show this is well-defined, we must show it is independent of the choice of $\psi$ and the choice of representative in the stable equivalence class of $(\varphi, \zeta)$.

By Proposition, if $\psi': E(\xi) \to \widetilde{E(\xi)}$ is any other p.d. bundle map, there exists a diff. bundle equivalence $\lambda : E(\xi) \to E(\xi)$ such that

$$
\begin{array}{ccc}
E(\xi) & \xrightarrow{\psi} & E(\xi) \\
\downarrow & & \downarrow \\
\widetilde{E(\xi)} & \xrightarrow{\lambda} & \widetilde{E(\xi)}
\end{array}
$$

commutes up to a p.d. bundle isotopy. It follows that $\psi\varphi$ and $\psi'\varphi$ define concordant smoothings.

It is clear that $(\varphi, \zeta)$ and $((\varphi, 1), \varphi + 1)$, $(\varphi, 1) : (K \times R^n) \times R \to E(\xi) \times R$, define concordant smoothings. Now suppose $(\varphi_1, \zeta_1)$ is equivalent to $(\varphi_2, \zeta_2)$; i.e. we are given $\varphi : K \times I \times R^n \to E(\xi)$, $\varphi$ restricting to $(\varphi_1, \zeta_1)$, $(\varphi_2, \zeta_2)$ resp. at 0 and 1. Again there exists a p.d. bundle map $\psi : E(\xi) \to \widetilde{E(\xi)}$, $E(\xi)$ the diff. bundle over $M \times I$, $\psi$ covering $(f_0, 1) : K \times I \to M_0 \times I$. Then by the Cairns–Hirsch theorem, $\psi\varphi : K \times I \times R^n \to \widetilde{E(\xi)}$ defines a concordance between the smoothings defined by $\psi\varphi_1$ and $\psi\varphi_2$.

Hence the map from stable equivalence classes to concordance classes is well-defined.

Let $\rho : T \to C_0$ be the map defined above.

**Theorem (6.1).**

$$
\begin{array}{ccc}
\widetilde{K, O} & \xrightarrow{\beta} & \widetilde{K, PD} \\
\downarrow & & \downarrow \\
\widetilde{K, BO} & \xrightarrow{\rho} & \widetilde{K, BPL}
\end{array}
$$

is commutative, and hence $\rho$ is an isomorphism of base pointed sets with operators.

**Proof.** (a) That $\zeta \rho = \rho$ is immediate from the definition of $\rho$.

(b) Let $(g) \in [\widetilde{K, PD}]$, $(\varphi, \zeta) \in t \in T$. Then $\lambda((g), t)$ is represented by $\varphi \oplus g : K \times R^n \times R^m \to E(\xi) \times R^m \rho((g), t)$ is determined by the Cairns–Hirsch theorem from $\varphi \oplus g : K \times R^n \times R^m \to E(\xi) \times R^m$. But $\psi \oplus g$ is p.d. isotopic to $\psi' \oplus g$, where

$$
\phi' : K \times R^n \to \widetilde{E(\xi)}_1
$$
where \((M_1, f_1) \in \rho(t)\). Then \(f_1 + g : K \times R^m \to M_1 \times R^m\) is p.d. isotopic to
\[
h : K \times R^m \cong M_1 \times R^m,
\]
where \((M_2, f_2) \in \lambda(\{(g), \rho(t)\})\). But then \((d_1 \times 1)_*(\{(f_1 \times 1) \oplus g\})\) and hence \(\varphi \oplus g\) is p.d. isotopic to \((d_1 \times 1)_*(1 \times d_2)_*(f_2 \times 1 \times 1)\), i.e. \((M_2, f_2) \in \rho(\lambda(g), t)\). Hence \(\rho \lambda = \lambda\).

(c) Since \(\rho : T \to C_0\) is a homomorphism of sets with group of operators \([\tilde{K}, PD]\), the usual 5—Lemma argument applies to show that \(\rho\) is an isomorphism. Q.E.D.

Define \(\sigma : T \to [\tilde{K}, PD/O]\) as follows:

Let \((\varphi, \xi) \in t \in T\), \(\varphi : K \times R^a \to E(\xi)\). Then since \(\varphi\) is p.d. homeomorphic over each simplex of \(K\), and \(E(\xi)\) is pasted together by elements of \(O_\sigma\), \(\varphi\) gives a well-defined map \(g_\varphi : \tilde{K} \to PD/O\). Further, equivalent pairs give homotopic maps. Consequently, we get a well-defined class \(\sigma(t)\).

**Theorem (6.2).**

\[
\begin{array}{ccc}
[K, O] & \xrightarrow{\lambda} & [\tilde{K}, PD] \\
\downarrow & & \downarrow \\
T & \xrightarrow{\zeta} & [\tilde{K}, BO] \\
\downarrow & & \downarrow \\
\tilde{K}, PD/O & \xrightarrow{\hat{p}} & [\tilde{K}, BPL]
\end{array}
\]

is commutative, and hence \(\sigma\) is an isomorphism of base-pointed sets with operators.

**Corollary.** \(T\) and hence \(C_0\) may be given a group structure, such that the exact sequences of Proposition (1, 2) become exact sequences of groups.

**Proof of Theorem.** (a) Let \((g) \in [\tilde{K}, PD]\) and \((\varphi, \xi) \in t \in T\). \(\lambda(g)\) is represented by \(\varphi \oplus g : K \times R^m \times R^a \to E(\xi) \times R^n\); clearly, \(\sigma(\varphi \oplus g, \xi \oplus 1)\) is just the Whitney sum; i.e. \(\lambda \sigma = \lambda\).

(b) Let \((\varphi, \xi) \in t \in T\). Let \(\tilde{P}\) be the total space of the associated principal s.s. \(O_n\) bundle to \(\xi\). Let \(f : \Delta_q \to K\) be in \(R^{(a)}\). Then \(F \in \tilde{P}^{(a)}\) is a p.d. bundle map \(F : \Delta_q \times R^a \to f^*(\xi)\) over \(f \in R^{(a)}\). Further, \(\varphi\) induces a unique p.d. homeomorphism \(\varphi_f\) such that

\[
\Delta_q \times R^a \xrightarrow{\varphi_f} f^*(\xi)
\]

\[
f \times 1
\]

\[
K \times R^a \xrightarrow{\varphi} E(\xi)
\]

commutes.

Then \(F^{-1} \varphi_f : \Delta_q \times R^a \to \Delta_q \times R^a\) is in \(PD_n^{(a)}\). Further \((\partial_i F)^{-1} \varphi_\partial_f = \partial_i (F^{-1} \varphi_f)\). Hence \(\varphi\) defines a s.s. map \(\tilde{\varphi} : \tilde{P} \to PD_n\). \(\tilde{\varphi}\) is a map of principal \(O_n\) bundles, since if \(R : \Delta_q \times R^a \to \Delta_q \times R^a\) is in \(O_n^{(a)}\), \(\tilde{\varphi}(FR) = R^{-1}(F^{-1} \varphi_f)\), which is just what the definition of right action of \(O_n\) on \(PD_n\) calls for.
Now the quotient map \( \tilde{K} \to PD/O \) induced by \( \phi \) is just the map \( g_\phi \) constructed in the definition of \( \sigma \). Further, \( \tilde{P} \to PD_n \subset PD_n \times U \) is an \( O_n \) bundle map which induces by passage to quotients

\[
\tilde{K} \overset{\zeta_\phi}{\longrightarrow} PD_n/O_n \subset PD_n \times U = BO_n
\]

Hence \( \zeta g_\phi \) is a classifying map for \( \zeta \), and \( \zeta \sigma = \zeta \).

(c) Again the \( S \)–Lemma argument shows that \( \sigma \) is an isomorphism of sets with a group of operators. Q.E.D.

From Theorem (6.1) and (6.2), we have \( C_0 \cong [\tilde{K}, PD/O] \); i.e.

**Theorem (6.3).** Let \( K \) be a combinatorial manifold (without boundary), which admits a smoothing \( M_0 \), then the concordance classes of smoothings of \( K \) are in 1–1 correspondence with the abelian group \( [\tilde{K}, PD/O] \) such that the class of \( M_0 \) corresponds to the identity element.

(Theorem (6.3) was announced by Mazur in Seattle)

**Remark.** Using Hirsch [2] it is easy to generalize Theorem (6.3) to manifolds with boundary.

**Corollary (1) (Hirsch–Mazur).** \( \pi_n(PD/O) \cong \Gamma_n \), the group of differentiable structures on \( S^n \) (under connected sum).

**Proof.** \( \pi_n(PD/O) \cong C_0(S^n) \) by the above. But since every n.s. p.d. homeomorphism of \( S^n \) onto \( S^n \) is p.d. isotopic to the identity, two smoothings, which are diffeomorphic, are concordant. Hence as sets \( C_0(S^n) = \Gamma_n \). If the base point of \( C_0 \) is taken to be the standard sphere, then we may show that \( C_0(S^n) \) with the group structure induced from \( \pi_n(PD/O) \) is group isomorphic to \( \Gamma_n \).

Note first, that we may define an addition in \( T \) by taking Whitney sum of trivial triangulations. Thus \( \sigma : T \to [\tilde{K}, PD/O] \) is obviously additive, so that the group structure in \( T \) is given by Whitney sum.

Now Whitney sum of vector bundles over a sphere corresponds stably to connected sum of bundles. Defining connected sum of trivializations (stably) in corresponding fashion, we see that under \( \rho : T \to C_0 \), Whitney sum of trivializations, corresponds to connected sum of spheres.

**Lemma (Milnor).** \( \pi_n(BO) \overset{p}{\to} \pi_n(BPL) \) is a monomorphism (and hence \( \pi(n) \to \pi(n)PD \) is a monomorphism).

This follows from Theorems (6.3) and (2.4), and the fact that every homotopy sphere has a stably trivial normal bundle. See [3].

**Theorem (Hirsch–Mazur).**

\[
O \overset{p}{\longrightarrow} \pi_n(BO) \overset{q}{\longrightarrow} \pi_n(BPL) \overset{\rho}{\longrightarrow} \Gamma_{n-1} \overset{q}{\longrightarrow} O
\]

is exact, where \( q : \pi_n(BPL) \cong \pi_{n-1}(PL) \cong \pi_{n-1}(PD) \to \pi_{n-1}(PD/O) \cong \Gamma_{n-1} \).

**Proof.** This follows from the above Lemma and Corollary (1).
§7. CONCORDANCE CLASSES OF SMOOTHINGS OF A VECTOR BUNDLE AND SMOOTHINGS OF IMBEDDINGS

Let \( \eta \) be a p.d. vector bundle over a unbounded combinatorial manifold \( K \), and let \((E(\mu), \varphi)\) be a triangulation of \( E(\eta) \). We wish to show

**Theorem (7.1).** There exists a 1–1 correspondence between concordance classes of smoothings of \( K \) and concordance classes of smoothings of \( E(\mu) \). Further, this correspondence is obtained by assigning to \((M_\alpha, f_\alpha)\), where \( f_\alpha : K \to M_\alpha \) the concordance class of \((E(\eta) \alpha, \varphi_\alpha)\), where \( \varphi_\alpha : E(\mu) \to E(\eta) \alpha \) is the induced triangulation given by \( \varphi \), and \( E(\eta) \alpha \) is the total space of differentiable vector bundles defined by \( \eta \) over \( M_\alpha \).

**Proof.** Let \( p : T(K) \to C_0(K) \) be as above. Let \( c \in C_0, \) and \( t = p^{-1}(c) \). Let \((\psi, \xi) \in T_K \); i.e., \( \xi \) is a p.d. vector bundle over \( K \) and \( \psi : K \times R^n \to E(\xi) \) is a trivial triangulation. Let \( p : E(\mu) \to K \) be the p.l. projection map. Then \((p*\psi, p*\xi) \in T(E(\mu))\) where

\[
\begin{array}{ccc}
E(\mu) \times R^n & \xrightarrow{p*\psi} & E(p*\xi) \\
p \times 1 & \searrow & \downarrow p \\
K \times R^n & \xrightarrow{\psi} & E(\xi)
\end{array}
\]

commutes.

\( E(p*\xi) = \{(x, y) \in E(\mu) \times E(\xi) \mid p(x) = \pi(y)\}, \) \( \pi : E(\xi) \to K \) the projection \( p*\psi(x, r) = (x, \psi(p(x), r)), p*(x, y) = y. \)

We define \( p* : T(K) \to T(E(\mu)) \) by \( p*(t_\alpha) = \{(p*(\psi), p*\xi)\}. \) Similarly, if \( s : K \to E(\mu) \) is the zero-cross-section, then \( s* : T(E(\mu)) \to T(K), \) and \( s*p* = 1. \) This shows that \( p* \) is 1–1 into.

On the other hand, since \( s(K) \) is a p.l. deformation retract of \( E(\mu) \), we have a homotopy \( H : E(\mu) \times I \to E(\mu) \) such that \( H_0 = 1, H_1 = sp. \) Given any trivially triangulated p.d. vector bundle \((\psi, \xi) \in T_E(E(\mu)) \) over \( E(\mu), \) \( E(H*\xi) \simeq E(\xi) \times I, \) and \( H*\psi : E(\mu) \times I \times R^n \to E(H*\xi) \simeq E(\xi) \times I \) gives an equivalence between \((p*s*\psi, p*s*\xi)\) and \((\psi, \xi), \) showing that \( t_{E(\mu)} = p*s*t_{E(\mu)}, \) i.e., \( p*s* = 1, \) and \( p* \) is 1–1 onto. (The fact that \( p* \) is 1–1 may also be obtained from the fact that \([E(\mu), PD/O] \simeq [\tilde{K}, PD/O]\).

Now let \((M_\alpha, f_\alpha) \in c, \) then \( t = p^{-1}(c) \) is represented by \((\psi, \xi), \) such that \( \psi : K \times R^n \to E(\xi) \); where \( E(\xi) \) is the diff. vector bundle over \( M_\alpha, \) is p.d. isotopic to

\[
\psi' : K \times R^n \xrightarrow{f_\alpha \times 1} M_\alpha \times R^n \xrightarrow{d} E(\xi) \,
\]

Then \((p*\psi, p*\xi)\) defines a smoothing in \( \rho(p*c) \) on \( E(\mu) \) from the Hirsch product theorem using \( p*\psi : E(\mu) \times R^n \to E(p*\xi), \) where \( E(p*\xi) \) is the diff. vector bundle over \( E(\eta) \).

We wish to show that this smoothing is \((E(\eta) \alpha, \varphi_\alpha)\)

\[
E(p*\xi) = E(\pi*\eta) \quad \text{and we have the commutative diagram}
\]

\[
\begin{array}{ccc}
E(\mu) \times R^n & \xrightarrow{p*\psi} & E(p*\xi) \\
K \times R^n & \xrightarrow{\varphi} & E(\xi)
\end{array}
\]
Consider the p.d. vector bundle $E(\psi^*\pi^*\eta) = E(\eta) \times R^n$, we have

\[
\begin{array}{c}
E(\eta) \times R^n \\
E(\mu) \times R^n \\
K \times R^n
\end{array}
\]

\[
\begin{array}{c}
\xrightarrow{\varphi \times 1} \\
\xrightarrow{\psi} \\
\xrightarrow{\text{identity}}
\end{array}
\]

\[
\begin{array}{c}
E\left(\psi^*\pi^*\eta\right) \\
E(\pi^*\eta)_0 \\
E(\xi)_0
\end{array}
\]

commuting.

The p.d. isotopy of $\psi$ to $\psi'$ is covered by a p.d. bundle isotopy of $\tilde{\psi}$ to $\tilde{\psi}'$. But then

\[
\begin{array}{c}
E(\mu) \times R^n \\
K \times R^n
\end{array}
\]

\[
\begin{array}{c}
\xrightarrow{\varphi \times 1} \\
\xrightarrow{d} \\
\xrightarrow{f \times 1}
\end{array}
\]

\[
\begin{array}{c}
E(\pi^*\eta)_0 \\
E(\xi)_0
\end{array}
\]

commutes.

Since $p^*\psi$ is p.d. isotopic to $\tilde{d}(\varphi_x \times 1)$, $(p^*\psi, p^*\xi)$ defines the smoothing $(E(\eta)_x, \varphi_x)$; i.e. $\rho \rho^*\rho^{-1}\{(M_x, f_x)\} = \{(E(\eta)_x, \varphi_x)\}$. This proves Theorem (7.1).

**Theorem (7.2).** Let $\mu$ be an $r$-dimensional microbundle over a combinatorial manifold $K^n$, and $i: E(\mu) \to V^{n+r}$ be a p.d. imbedding in a smooth manifold $V$. Then if $\mu$ is a triangulation of some p.d. vector bundle $\xi$, there exists a smoothing $M_x$ of $K$ such that $i$ is concordant to a smooth imbedding $E(\xi)_x$ in $V$.

Explicitly, there exists a p.d. imbedding $\lambda: E(\mu) \times I \to V \times I$ such that $\lambda_0 = i : E(\mu) \times 0 \to V \times 0$ and $\lambda_1 : E(\mu) \times 1 \to V \times 1$ may be factored

\[
\begin{array}{c}
E(\mu) \\
E(\xi)_x
\end{array}
\]

\[
\xrightarrow{\varphi_x} \\
\xrightarrow{\lambda_1}
\]

where $\varphi : E(\mu) \to E(\xi)$ is the triangulation, and $d$ is a smooth imbedding.

**Proof.** $i : E(\mu) \to V$ induces a smoothing $(g, E(\mu)_\tilde{g})$ of $E(\mu)$, such that

\[
\begin{array}{c}
E(\mu) \\
E(\mu)_\tilde{g}
\end{array}
\]

\[
\xrightarrow{i} \\
\xrightarrow{\varphi}
\]

\[
\xrightarrow{d_0}
\]

\[
\xrightarrow{\psi}
\]

\[
\xrightarrow{\rho}
\]

\[
\xrightarrow{\rho^*\rho}
\]

\[
\xrightarrow{\text{commutes, where } d_0 \text{ is smooth}}
\]

By Theorem (1), $(g, E(\mu)_\tilde{g})$ is concordant to some $(E(\xi)_x, \varphi_x)$. If $\lambda : E(\mu) \times I \to W$ is this concordance, then there is a diffeomorphism $e : E(\mu)_{\tilde{g}} \times I \to W$, such that $e_0g = \lambda_0$. Take $\lambda = (d_0 \times 1) \circ e^{-1} \circ \tilde{\lambda}$. Since $\tilde{\lambda}_1 = d_1 \varphi_x$, for some diffeomorphism $d_1$, $\lambda_1 = d_\varphi_x$, where $d = d_0e_1^{-1}d_1$ is a diffeomorphism.
**Theorem (7.3).** Let \( i : K \to V \) be a p.l. imbedding of a combinatorial manifold in a smooth manifold \( V \), w.r.t \( f : L \to V \) a smooth triangulation. Then there exists a non-singular p.d. homeomorphism \( h : V \to V \) such that \( hi(K) \) is a smooth submanifold with normal vector bundle \( \xi \); if and only if \( i(K) \) has a normal microbundle \( \mu \) which triangulates \( \xi \).

**Proof.** (a) Only if

Let \( \varphi : E(\mu) \to E(\xi) \subset V \) be the triangulation. Then \( \varphi \) is p.d. isotopic, relative to the zero section, to a p.l. imbedding \( \varphi_1 \) w.r.t the triangulation \( hf : L \to V \). Then \( h^{-1}\varphi_1 : E(\mu) \to V \) is a p.l. imbedding which extends the imbedding \( i : K \to V \).

(b) If

By Theorem (7.2), if \( i(K) \) has a normal microbundle \( \mu \) which triangulates \( \xi \), there exists a p.d. imbedding \( \lambda : E(\mu) \times I \to V \times I \) such that \( \lambda_0 : E(\mu) \to V \) is a p.l. imbedding which extends \( t \), and \( \lambda_1 = d\varphi_0 ; \) where \( d \) is a diffeomorphism, and \( E(\xi) \) is a differentiable vector bundle over a smoothing \( M_\delta \) of \( K \), which is equivalent as a vector bundle to \( \xi \). Let \( N \) be a regular neighborhood of the zero-section in \( E(\mu) \). Then \( \lambda_0(N) \) is a combinatorial submanifold with boundary of the same dimension as \( V \). Let \( N_1 \) be the second regular neighborhood of \( N \) in \( E(\mu) \); then \( N_1 = N \cup \partial N \times I \). It follows by the Cairns–Hirsch theorem, that \( \lambda : (N_1 \times I, N_1 \times \partial I) \to (V \times I, V \times \partial I) \) is p.d. isotopic, relative to \( (N \times I, N \times \partial I) \) to a p.d. imbedding \( \tilde{\lambda} \), such that \( \tilde{\lambda}(\partial N_1 \times I) \) is a smooth submanifold. Now \( \tilde{\lambda}(\partial N_1 \times I) \) has a smooth product neighborhood \( T \) in \( V \times I \). See Fig. 1.

Then \( V \) is a smooth manifold (after smoothing corners).

---

**FIG. 1.**

---

**FIG. 2.**
Let $V = (V - T_0)^- \cup \partial T \cup T_1$. This is represented by heavy line in Fig. 1. Since $\partial T$ is diffeomorphic to $\partial V_0 \times I$, and $\partial (N_1 \times 0)$ is homeomorphic to $\partial (N_1 \times 0)$, there exists a non-singular p.d. homeomorphism $h : V \to \overline{V}$ such that $h(K)$ is a smooth submanifold of $\overline{V}$ with normal bundle $\xi$. It remains to show that $V$ is diffeomorphic to $\overline{V}$.

Extend the left boundary of $V \times I$, then the region between the new boundary and $\overline{V}$ is a smooth manifold which is combinatorially a product (see Fig. 2). Hence $V$ is diffeomorphic to $\overline{V}$ by Munkres [8]-Thom [10].
